Taking, first, the syphilides, the lecturer pointed out that in the average case of undoubted syphilis there was first a period of incubation of about three weeks' duration; then a primary period, also of about three weeks, during which the spirochaetes multiplied locally, but the Wassermann reaction was negative; after this a second incubation period between the first appearance of the Wassermann reaction and the development of the secondary eruptions, when the various forms of secondary syphilides became successively less extensive, but larger in size, and the Wassermann tended to diminish; next a period of freedom from symptoms, with the Wassermann negative, and finally a tertiary period in which the Wassermann reaction was positive in from 60 to 80 per cent. of the cases. The secondary syphilides represented the allergic reactions of the skin against the spirochaetes.

Turning to the tuberculides, the lecturer said that although tuberculosis could not as readily as syphilis be divided into primary, secondary, and tertiary periods, nevertheless some such division could be made in the majority of cases. The term "tuberculides" was proposed by Darier in 1896 for a group of eruptions occurring in association with other manifestations of tuberculosis. The lecturer could not accept Darier's classification in its entirety, as, for example, the inclusion of the lupus sarcoid or lupoid of Boeck, but in general, in the mechanism of their production, the tuberculides resembled the secondary and tertiary eruptions of syphilis.

With regard to the trichophytides, these were generally eruptions, comparable with the others, occurring as a result of local infection of the skin with a ringworm fungus. As in the majority of cases of syphilis, there was a primary lesion of the skin, developing at the site of inoculation, as a result of which the skin as a whole might become sensitized. Only in the severer forms of suppurative ringworm were secondary eruptions likely to be seen. In some cases the eruptions were due to a dissemination of the fungus spores through the blood stream; in others they resulted from exogenous spread.

Allergic Reaction to Streptococcal Infection.

Some years ago, Dr. Barber continued, he had himself proposed the name "streptococcides" to designate certain eruptions which were allergic reactions to streptococcal infection, comparable to the other groups. Syphilis, tuberculosis, and ringworm were well-defined and established diseases, and a definite diagnosis of one or the other could usually be substantiated; but the streptococcal group of organisms was in a state of flux. Strains that in the laboratory were apparently identical might have very different pathological properties, and it was often impossible to furnish definite proof that a given condition was due to streptococcal infection. Nevertheless, the establishment of a group of streptococcides was justified by the evidence which had accumulated from independent sources during the last few years. The great interest of such a comparison lay in the fact that with certain types of cutaneous or subcutaneous reaction not only were the clinical appearances much the same whatever the organism represented, but the histological picture was similar in form, showing that the defensive allergic reactions to organisms might depend rather on the tissues infected than on the nature of the infection. All these eruptions which he had called the exanthematides were dependent on two factors: an allergic state of the skin towards the particular infecting organism responsible, and the conveyance to the skin of the organism or its toxin by the blood stream. They represented antibody-antigen reactions designed to destroy the organism or toxins *in situ*.

The lecturer discussed a number of types of eruption from the point of view of this classification. With regard to erythema nodosum—a term which, like erythema multiforme, was used loosely—he thought it was clear that this type of eruption was in rather rare cases a tuberculide and, also rarely, a trichophytide, witness cases cited by Bloch and others. Erythema nodosum was probably not a specific morbid entity; in the majority of cases it was of streptococcal origin.

The Skin as a Defensive Mechanism.

The significance of the cutaneous and intracutaneous tests with tuberculin, trichophytin, and similar extracts the lecturer considered to lie only in affording evidence that the skin was sensitized to the specific antigenic substance of the infective organism. It followed that a positive reaction indicated that infection with a particular organism had taken place, and that there was continuing allergy towards it.

In conclusion, he wished to raise a question which to his mind was of profound interest and importance—namely, the extent to which, when active infection was present, the cutaneous manifestations of such infection constituted a protection against invasion of deeper organs. Might not the rash represent part at any rate of the body's campaign against the invading organisms, and recovery from an acute exanthem be partly dependent upon the rash? The evidence in favour of this view was strong. The popular idea that the eruption was an effort to drive out infection, and that care must be taken not to drive it in again, should not be too readily scorned as superstition. In the case of the streptococcides, could not the same defensive role against visceral damage be detected? The allergic condition of the skin was to some extent a protective mechanism against the involvement of the more vital organs.

SATURDAY, MARCH 16TH, 1929.

THE STATISTICS OF MORBIDITY.

A DOCUMENT recently printed for the Health Section of the League of Nations[1] raises, both directly and indirectly, an interesting question—namely, whether records of sickness can be made to yield information of the same value as records of mortality. The document is an essay by the distinguished medical statistician Dr. E. Roesle of the Reichsgesundheitsamt, and his principal object is to provide materials for the preparation of a list of causes of morbidity designed to play a part like that played in the field of mortality statistics by the well-known International Classification of Causes of Death. Prima facie there is a strong case in favour of Dr. Roesle's proposals. Nobody now doubts the utility of international comparisons of mortality statistics (when made with common sense and discretion), or denies that an internationally agreed classification has increased the precision of such comparisons. It will also be generally agreed that, as causes of inefficiency and suffering, there are many definable forms of illness which make hardly any direct contributions to the statistics of mortality. Hence, it may be urged, international comparisons of morbidity rates may, from the hygienic point of view, be quite as important as comparisons of specific death rates.

Dr. Roesle points out that there is a lack of agreement between the several national and international authorities upon principles of classification, and, after a very careful analysis of the data of various health insurance offices in Germany and Hungary, as well as of seemingly comprehensive returns from Moscow, he makes detailed proposals which, *inter alia*, would help to remove some of the more glaring discrepancies between the data. This is a useful piece of work. It is certain that when the returns of two populations on approximately the same cultural and industrial level—for example, two industrial cities of the same State—give incidence rates of, say, "neurasthenia" differing by hundreds per cent., the medical practitioners in the two places are not using the word "neurasthenia" in the same sense, and it is possible that one may discover what is the surrogate term in the place with little "neurasthenia." If that possibility can be implemented, then the amalgamation of the two headings may permit of a useful comparison. These are all solid arguments in favour of such collations of data as Dr. Roesle has made; but it is possible that statisticians, being human, may have more faith in the power of their art of classification and analysis than it merits. We suggest that data of morbidity differ intrinsically from those of mortality. When a practitioner of medicine has watched an illness from its earliest stages to the death of the patient he can, in many instances, pass beyond a symptomatic to a complete diagnosis. But in minor illnesses, or even in serious illnesses only under observation at the beginning, that is not possible. It is easy for an office statistician, learned in official nosologies, to be contemptuous of the frequency with which "merely symptomatic diagnoses"—such as "debility," "nervous debility," "gastric catarrh"—occur in records of morbidity, and to urge the importance of more scientific definition. Actually much minor illness cannot be truthfully defined more strictly, and it is not scientific, but realistic, in a mediaeval sense, to pretend that it can. Chaucer's Doctor of Physic (if he knew his Galen as well as the poet said he did) had a more detailed nosological classification in his memory than even a student of 1929 on the eve of his final examination (we remember a distinguished surgeon saying that nobody but a student the night before the final "Conjoint" could precisely classify neoplasms). There is, we think, a danger that this realism may lead us to mistake a mere elaboration of ignorance—inevitable ignorance—for knowledge.

Since all available statistics of general morbidity (other than those of Russia) are based upon the records of insured persons, a large majority of whom are industrially employed, it is natural to expect that the analysis of the data should throw light upon the problems of industrial hygiene so much discussed. Certainly, in view of the dogmatic statements respecting the deleteriousness of this or that factor of industrial life often made without any evidence, light is needed. But an examination of some recent reports of the Industrial Fatigue Research Board would satisfy any reader that the study even of general morbidity—making but the broadest classifications by causes—is a very difficult matter. On February 19th Dr. A. B. Hill read, at a meeting of the Royal Statistical Society, a useful paper which illustrated some of the difficulties. He pointed out, *inter alia*, that "recorded" illnesses have a predilection for beginning on a Monday and ending on a Saturday. Whether this means that those who might have gone back to work at the end of the week did not, or that those who ought to have stayed at home on Monday decided to try not to lose more time, is an interesting point; the *fact*, whatever its interpretation, illustrates the distinction between data of recorded morbidity and of recorded mortality. Apart from traffic accidents, and the doubtful case of overlying of infants, there is no reason to suppose that one day of the week is more deadly than another.

We need not labour the point; it will be clear enough to practitioners of medicine. The time is past when careful classification of records and their accurate statistical analysis were sneered at as mere juggling with figures. That foolish attitude should not, however, be replaced by a belief that almost any records can be made scientifically comparable if only statisticians of sufficient eminence will classify and analyse them.

SCIENTIFIC LITERATURE.

THE latest edition of Mansfield Clark's classical work on *The Determination of Hydrogen Ions*, reviewed in another column, is full of valuable information, but there is nothing in the book of greater general interest to scientific workers than the figure, inserted in the preface, which shows the time distribution of the references contained in the bibliography. This figure shows that in 1910 about fifty papers were published on the subject of hydrogen-ion concentration, and that this number has doubled every four years, and now approaches 1,500 per annum. The curve suggests that the 2,000 level will be reached in another five or six years. As the author says: "The situation has made obsolete some of the old ideals of scholarship. It has made trivial all available facilities of library, abstract, and review. It has made the monograph almost futile. It has made ridiculous him who claims to combine thorough investigation with thorough *re*-search." In writing this Professor Mansfield Clark

conveys the experience and opinions of all who are compelled to cover popular fields of scientific research. Undoubtedly scientific workers are threatened with the necessity of choosing whether they will spend their energy and time in keeping up with the literature and writing monographs, or whether they will devote themselves to original research. Unfortunately, however, it is only those with a first-hand knowledge of a subject who can write a monograph that is worth reading, because such persons alone can sort out the grain from the chaff. It is a pity that Professor Mansfield Clark did not supplement his interesting curve by a second curve showing the number of papers per annum that were of any real importance; it is safe to say that the two curves would have followed very different courses.

There is no doubt that scientific workers will have to depend more and more on authoritative monographs for an account of the existing knowledge in any subject, and those who devote themselves to the tedious task of producing such works deserve the gratitude of their fellows. The flood of scientific literature is, however, being augmented unnecessarily, and it could be checked if public opinion in the world of science would show its firm disapproval of certain practices. The publication of substantially the same article in several different journals, and possibly in different languages, is, to say the least, a misdemeanour. Medical science in particular suffers from this practice. We have heard the suggestion that it would be checked if contributors were charged a special high advertisement rate for all articles that were found to have appeared elsewhere. The habit of estimating the merits of candidates for scientific posts or the activity of university departments by the weight of published material is also responsible for a large amount of over-publication, and this would cease if attention were paid to quality and not to quantity.

Finally, there is the problem of publishers who run scientific journals for profit, and aim at producing the greatest possible number of volumes a year, regardless of the quality of the articles published therein. This evil is not prevalent in this country, but it is rampant in Germany. The funds and shelf space of libraries are exhausted by certain "wastepaper basket" journals, whose volumes increase yearly in geometrical progression. There is only one remedy for this—namely, the organized boycott of journals which do not maintain a certain critical standard of editorship. Such a boycott has been mooted before now, but it has failed because there are so many libraries in Europe, and particularly in America, to whom expense is of less consequence than the completeness with which they cover the literature of science. The exploitation of scientific institutions in this manner will only be prevented when it is generally recognized that the encouragement of a scientific journal that maintains no critical editorship is not merely a waste of money, but actually handicaps the progress of science.

THE LOCAL GOVERNMENT BILL: CONSULTATION WITH THE PROFESSION.

THE suggestion made by Lord Dawson in the course of the consideration of the Local Government Bill by the House of Lords that a clause should be inserted requiring the council of a county or county borough to consult with (1) any body in its area representing voluntary hospitals or their medical and surgical staffs, and (2) any body in its area representing the general body of the medical profession, before settling its administrative arrangements, has been received sympathetically by the Government. We believe there is no doubt that the former of these suggested consultations will be imposed on the councils; but we would strongly urge the Government to accept for inclusion in the bill in its proper place the latter consultation also. It is of vast importance that private medical practitioners, whether general or consultant, should be brought into intimate connexion with the public health services, and a provision such as that indicated would be a very great advance in this direction; it would in many cases prevent local difficulties which are apt to render the public health medical services much less efficient and useful to the public than they should be.

THE LEAGUE OF NATIONS AND THE OPIUM QUESTION.

FULL particulars of the astounding case of illicit trafficking in morphine, heroin, and cocaine, to which reference was made in the *Journal* of February 2nd (p. 213), are vouchsafed in the report to the Council of the League of Nations of the twelfth session of the Opium Advisory Committee, just published. The intermediary in this huge contraband enterprise was the Chemische Fabriek Naarden at Bussum, a few miles south-east of Amsterdam. During the year 1927 and the first half of 1928 nearly 1,000 kilograms of morphine, 3,000 kilograms of heroin, and 90 kilograms of cocaine, mainly derived from Basle, Mannheim, and Hamburg, were re-exported, chiefly to the Far East, Shanghai being the most common destination. The committee remarks that this factory at Bussum "probably dealt with about half the total annual world production of heroin," the alkaloid regarded as the most perilous in its illicit use, and whose manufacture is now prohibited in the United States. This centre for international contraband, now suppressed, appears to have escaped detection partly by these narcotics being treated as "in transit," and therefore not appearing in the statistics of import and export, and partly by their incorrect description as "pharmaceutical products," "mediums," or "perfumeries." Indeed, "every contrivance was used to render inquiries into the origin of the narcotics impossible." This traffic was admittedly "contrary to the spirit of the law" and to the terms of The Hague Convention of 1912 and that of Geneva of 1925. It serves abundantly to prove that the production of these dangerous drugs is grossly in excess of any conceivable medical or legitimate requirement, and amply justifies the contention of China that smuggling of European alkaloids into that country demands no less scrutiny than the exports of opium out of it. The Advisory Committee encounters grave difficulty in regard to the production of opium by the failure of Persia and Turkey, which probably between them raise a million kilograms of opium annually, to favour the League with any reports of their traffic. It is further deplored that "more than one-half of the States members of the League, including six members of the Council, have not yet ratified the Geneva Opium Convention of 1925." The committee gave consideration to a scheme, which has been adopted in Spain and is supported by the United States, for notification in advance by each State of its requirements of each of the drugs for a determined period. Reference has previously been made to this scheme in the *Journal*, but the committee did not think it advisable to take any action in regard to it. The new Permanent Central Opium Board met for the first time at Geneva during the sittings of the Opium Advisory Committee, and the possibility of overlap in their duties by the two bodies was considered, but no decision was arrived at in regard to the delimitation of their respective functions.

PARASITIC PROBLEMS OF THE WEST INDIES.

In discussing some of the parasitic problems of the British West Indies at a meeting of the Section of Tropical Diseases of the Royal Society of Medicine on March 7th, Dr. T. W. M. Cameron pointed out that these islands, once the most important British colonies, now form a backwater of the Empire, and, apart from Jamaica, Trinidad, and Barbados, lie off the main steamship lines. The Lesser Antilles form a double crescent from Trinidad in the south to St. Kitts in the north. The inner range is volcanic, and the outer coral, while Trinidad is largely composed of metamorphic rocks. All are tropical, but the intense summer heats are mitigated to a great extent by the trade winds. The rainfall is abundant, and all except the most southern are liable to visitations from very severe hurricanes, which do an enormous amount of damage. The important industries are sugar, cocoa, coconuts, spices, sea-island cotton, and citrous fruits; while Trinidad has besides a very profitable oil industry. In general, the water supply is good and the sanitation poor, but exceptions to both exist. Port of Spain, for example, is one of the most sanitary and up-to-date cities in the tropics, with an excellent water supply and water sewage. In Antigua much has been done to improve the very deficient water supply, and nowadays it is fairly adequate. The important diseases are tuberculosis, intestinal diseases, venereal disease, and yaws. Malaria is common, and a number of very troublesome animal parasites abound. Among the important insect pests are mosquitos of all kinds—the yellow fever mosquito being particularly active, although the disease itself is now absent. Sand-flies, larval mites, and jigger fleas also combine to worry the stranger, and in some islands extra assistance is rendered by snakes and blood-sucking bats. Malaria is endemic in all the islands except Montserrat and St. Kitts. Until 1927 it was absent also from Barbados, but in that year a serious outbreak occurred, and it has not yet been stamped out. Filariasis appears to be absent from Trinidad and Grenada, but it is very common in some of the other islands—especially Barbados, Antigua, and St. Kitts. Everywhere it is decreasing, and, as mosquito control continues to be energetically prosecuted, it should ultimately be stamped out. One of the commonest parasites in all the islands is *Ascaris lumbricoides*, the common roundworm, and locally it is attributed with considerable disease-causing properties. A similar worm, morphologically at least, occurs in pigs in many parts of the world; yet it is a curious fact that in the West Indies, where faeces disposal is poor, and where pigs are given every opportunity to become infected from human sources, the parasite scarcely ever occurs in pigs. It seems highly probable, therefore, that the human and porcine varieties of ascaris are quite distinct physiologically, and not mutually infective. *Schistosoma mansoni*, discovered in 1902 by Sir Patrick Manson in a patient from the West Indies, while present in many foreign islands, has only been notified from three British possessions there—Antigua, St. Kitts, and St. Lucia—and in the last instance only three cases have been reported. In Antigua the disease does not appear to be a severe one, and Dr. Cameron found no infected snails, although he was able experimentally to infect the *Planorbis* so common in the only stream in the island. In St. Kitts, on the other hand, in places where the parasite occurs there is a 20 per cent. infection; it is found, however, only in villages beside the permanent streams, and as there are no more than three of these the general health of the island is only slightly affected. St. Kitts is overrun with African monkeys, and these are infected too—but here again only near the streams. This raises an undoubted complication in eradication, as therapeutic measures alone, effective as they can be in the case of this parasite, cannot eradicate a disease in which there is a wild reservoir host. Snail eradication is the only method at present available. Hookworm disease is present in about 60 per cent. of the population in the southern islands, but is rare in those north of Guadeloupe. In Barbados—a coral island with a clay highland area on the windward side—there is an infection of 20 per cent. on the coral and 65 per cent. on the clay. In Antigua, an island with a coral belt, a clay belt, and a volcanic mountainous belt, the distribution is respectively 6, 12, and 32 per cent. This and ascaris are both potent factors in causing debility, anaemia, and general lack of energy. Both are carried by faeces, and both could be eradicated by an efficient sanitary system. It is difficult, however, to get the natives to use latrines, even where available, and unless the latrine habit can be cultivated no amount of treatment will eradicate the disease. This implies education and sanitary propaganda—a much more difficult task than it would appear at first sight, owing to the mentality of the peasants. It requires the judicious spending of considerable sums of money, and as most of the islands, except Trinidad, are in a poor state financially (which was accentuated by the recent hurricane), the prospects of eradication are not too bright. However, Canada has become interested in these islands, and she may be able to increase their prosperity. The authorities, civil and medical, are well aware of their responsibilities, but money is lacking, and there is little co-ordination among the islands. The suggestion of Sir Patrick Manson for a medically trained governor-general for all the colonies in this area is one which still merits serious consideration. Without health prosperity is impossible, and if the striving after health and after prosperity were both controlled by one person much could be done.

ESTIMATION OF ABILITY.

In 1927 the Medical Research Council published a report[1] embodying the results of a study in vocational guidance conducted during the period 1923–26 jointly by the Industrial Fatigue Research Board and the National Institute of Industrial Psychology. This experiment, the first of its kind to be carried out in Great Britain, was planned so as to demonstrate the possibilities of vocational guidance—in other words, to determine as completely as possible the nature and interrelation of the personal qualities of each child under investigation, rather than to obtain results of definitely practical value. It was limited accordingly to the study of only 100 children. In 1924, however, continuance of the research on a much larger scale was made possible through the generosity of the Carnegie United Kingdom Trust, and Mr. F. M. Earle, of the National Institute of Industrial Psychology, has carried out an investigation involving the comparison of a group of 600 children, each subjected to various kinds of intelligence tests, and on this basis given vocational guidance, with a similar untested control group about whose occupations no recommendations were made. The following up of these two groups to determine the success or failure of each individual child in relation to the vocational advice he has received, or to the vocation he has chosen independently, is still proceeding, and the results will not be ready for publication for some little time. Meanwhile, however, the Medical Research Council has issued a report,[2] prepared by Mr. F. M. Earle and his fellow workers, on the use of performance tests—that is, of tests in which intelligence is measured by the performance of some specific act, and without recourse to language, either oral or written—in vocational guidance. In this report the results of

[1] Report No. 33. London: H.M. Stationery Office. 1926. 4s. net.
[2] Report No. 53. The Use of Performance Tests of Intelligence in Vocational Guidance: An Investigation conducted for the National Institute of Industrial Psychology. By F. M. Earle, M.Ed., B.Sc., M. Milner, B.Sc., and other Members of its Staff. London: H.M. Stationery Office. 1929. 2s. 6d. net.

performance tests have been analysed, first to determine whether they are satisfactory instruments of measurement, and secondly, to discover the basic abilities required to carry them out successfully. The use of performance tests has been advocated for several reasons. They are of value in the examination of children at low mental levels, and of children who may be unacquainted with the particular language it is decided to employ. The Binet tests favour children with verbal fluency, who may, however, be lacking in qualities of reasoning, judgement, and foresight. Though these tests may bear a close relation to the abilities demanded for success in school, they often give little indication of a child's prospects of success in occupational life. It is found, furthermore, that some children are more interested in the concrete situation involved in the performance tests than in the more abstract problems set by the verbal tests, and are likely, therefore, to put more effort into their solution. The children studied were at school-leaving age, the great majority being just under 14, and the performance tests used were revised from the series described by F. Gaw,[1] and standardized by her for English children. It was found that as affording a "composite" age scale the complete series of tests had its limitations, and that the tests could not be combined into a satisfactory single "total score." Accordingly, an endeavour was made to determine the exact part played by general intelligence in securing success, and to obtain information as to the relative importance of the specific abilities involved. It was found that abilities measured by the tests did not, as appears to be the case with general intelligence, develop uniformly from age to age. Using the mental age method of interpretation, a boy or girl may have a mental age of 16 in one test and of 10 in another, which is confusing when the tests are measures of abilities other than, as well as of, intelligence. For each separate test it was necessary to differentiate between the relative parts played by general intelligence and by specific abilities in achieving successful performance. The investigation suggests that special abilities tend to show themselves more definitely at about puberty than previously. The composite mental age norm derived from the results of a number of performance tests is therefore held to be more reliable for younger children, whose success depends mainly on general intelligence, than for children at the age of 13 or 14. It may also be more reliable for girls who, in performing the tests, seem to use general intelligence rather than special abilities. The correlation coefficient of the performance tests with the Binet test was 0.94 for girls as against 0.44 for boys. That there is a factor common to all the performance tests is certain; but whether it consists only of the general factor common to all mental tests, or of this factor in combination with some group factor, cannot be decided on the evidence of the results so far obtained. The investigators record the fact that the situations created by the performance of the tests rouse significant reactions, the systematic observation of which is likely to prove valuable in determining whether or not the child is likely to develop suitable adjustment to particular kinds of work.

[1] Report No. 31. London: H.M. Stationery Office. 1925. 2s. 6d. net.

LORD FINLAY.

VISCOUNT FINLAY OF NOVAR, who died on March 9th, aged 87, will long be remembered as a great jurist who held the highest offices open to the profession of law. He was also (if the Scots phrase may be used of one so eminent) a "stickit doctor," having graduated M.B. at the University of Edinburgh at the age of 22. The early intention of making medicine his career was no doubt due to home influences, for his father, Dr. William Finlay, was a Fellow of the Royal College of Physicians of Edinburgh, and long enjoyed a good practice in that city. Robert Finlay, however, relinquished medicine soon after becoming qualified; he never practised, and his name disappeared many years ago from the *Medical Register*. The law claimed his whole energies and gave his peculiar gifts their natural scope. For nearly half a century—from 1867 until his appointment as Lord Chancellor in 1916—he practised with great and deserved success at the Bar, and for ten years was a Law Officer of the Crown. In 1920 he was appointed the British member of the Permanent Court of Arbitration at The Hague, and in the following year a member of the International Court of Justice set up by the League of Nations Assembly. As Member of Parliament from 1910 to 1916 for the Universities of Edinburgh and St. Andrews, Sir Robert Finlay represented a constituency largely medical, and thus for a time regained touch in some measure with the profession to which he had first belonged. He would have attained high rank in any calling, but it is probable that the law gained more than medicine lost when, as a young medical graduate, Finlay came from Edinburgh to London to read for the Bar.

INFLUENZA.

IN the week ending March 2nd the death roll of influenza in the great towns of England and Wales again lengthened, from 1,764 to 2,183. These last two weeks have seen the largest returns since the pandemic years 1918–19; for the total in the worst week of the 1922 recrudescence was only 1,450. The notifications of primary pneumonia increased from 4,451 to 5,874, also a "record" figure. The local distribution of mortality and morbidity suggests that the epidemic was subsiding in Lancashire and in London, but still increasing in the Midlands, Yorkshire, and the North. In London and Lancashire the epidemic has developed synchronously. In both areas the maximum of notifications of pneumonia was in the week ending February 9th, and of deaths from influenza a fortnight later. In Yorkshire and the Midlands the notification rate of pneumonia did not begin to rise unmistakably until the London and Lancastrian maxima were passed, and in both areas the ratio of notifications to gross population is already larger than in the worst week of London. Birmingham was conspicuously affected in the week ending March 2nd, when deaths from influenza increased from 80 to 229. Clinical reports still speak of the mildness of type, and the age distribution of the deaths ascribed to influenza continues to select the aged.

PHYSICAL EXAMINATION FOR MOTOR DRIVERS.

FOLLOWING upon a resolution moved by Dr. Stella Churchill in the London County Council, the Public Control Committee of that authority has been considering whether all holders of motor drivers' licences should be required to undergo a physical examination. Under the existing law the county council, as licensing authority, has no power to refuse to grant a licence to drive a motor car unless the applicant is under the age of 17 years (14 years in the case of a motor cycle) or is disqualified from obtaining a licence. The committee has ascertained the practice in other countries, which appears to be widely divergent; in some countries a driving test is imposed, in others medical certificates have to be obtained, whilst in at least two countries both a medical examination and a driving test have to be passed. It has not been possible to obtain particulars as to the number of accidents attributable to the physical unfitness of the driver. Four of the eight London coroners have stated that there is no record during the past three years of any case of fatal accident in their districts being due to some physical defect of the driver which could have been ascertained by the making of a physical examination when he applied for a licence, and in no case do any of the London coroners state that a fatal accident resulted from the driver's physical disability, although this inference might be drawn in one or two cases.

In the view of the London County Council committee, the question at issue is a national one; it is at present being dealt with from that standpoint both by the Royal Commission on Transport, which has heard evidence as to the necessity or otherwise of instituting a physical test for applicants for licences, and in the Road Vehicles Regulation Bill, introduced into the House of Lords by Lord Cecil, and now under consideration by the Select Committee, which would require a person to satisfy the licensing authority that he was physically fit and competent. In these circumstances the Public Control Committee has, with some reason, decided to take no action. If there is need for a changed practice it should be met by a uniform policy applicable to the whole country.

EMIL VON BEHRING.

ONE of the greatest benefactors of humanity, Emil von Behring, the seventy-fifth anniversary of whose birth is being celebrated in Germany this week, was born at *Hansdorf, near Deutsch-Eylau, West Prussia, on March 15th, 1854*, the son of a schoolmaster, who was father of eleven other children. He started his professional career at the age of 26 as an army surgeon, and two years later, in 1882, published his first scientific work on the action of iodoform as an antiseptic. In 1888 he left the army, and the following year became Koch's assistant at the Hygienic Institute of Berlin, where two years later, in collaboration with Kitasato, he discovered tetanus antitoxin, and published his first article on diphtheria and tetanus antitoxin, for which he was awarded the prize of 50,000 francs by the Institut de France, and of 25,000 francs by the Académie de Médecine. At Christmas, 1891, he made the first trials of diphtheria antitoxin in von Bergmann's and Heubner's clinics at Berlin. In 1894 he was appointed professor of hygiene and bacteriology at Halle, and in 1895 occupied the corresponding chair at Marburg. Orders and distinctions in the following years were showered upon him by the learned societies of all European countries. In 1901 von Behring was made the first recipient of the Nobel Prize, in acknowledgement of his discovery of diphtheria antitoxin, and received the title of nobility. During the next four years he conducted experimental studies in connexion with the prevention of bovine tuberculosis, and in 1905 turned his attention to the collection of milk by aseptic methods and its preservation by formalin and hydrogen peroxide. Besides numerous shorter articles on the experimental therapeutics of anthrax and streptococcal infection, the hygiene of milk supply and water, and other subjects, von Behring was the author of books on blood serum therapy (1892), the etiological treatment of infectious diseases (1893), the history of diphtheria (1893), the control of diphtheria (1894), and the general treatment of infectious diseases (1898).

SIR E. FARQUHAR BUZZARD will deliver an address to the North Western Tuberculosis Society, in the Anatomy Theatre of the Medical School, Oxford Road, Manchester, on Thursday, March 21st, at 3.15 p.m., on tuberculosis and the nervous system. The meeting will be open, and the attendance of medical practitioners is cordially invited.

AT the next meeting of the Society for the Study of Inebriety on Tuesday, April 9th, at 4 o'clock, at 11, Chandos Street, Cavendish Square, W., Dr. J. D. Rolleston will open a discussion on "Alcohol in therapeutics."

THE British Association for the Advancement of Science, at the invitation of the Court of Common Council, will hold its centenary meeting in 1931 in London.

South Africa.

Passing of the Natal Medical Council.

AT the final meeting of the Natal Medical Council on December 14th, 1928, the president, Dr. D. Campbell-Watt, delivered a valedictory address, which is published in the issue of the *Journal of the Medical Association of South Africa* for January 12th. The president reminded his hearers that, in 1856, the Natal Medical Committee was formed; it was replaced later by the Natal Medical Board, which continued until the coming into operation of the Medical and Pharmacy Act of 1896, and the creation of the Natal Medical Council. This, like other provincial councils, was now being superseded by the Union Medical Council under the consolidating Medical and Pharmacy Act of 1928. The membership of the Natal Medical Council had always consisted of seven medical practitioners and one dentist; three of the seven, together with the dentist, were nominees of the Government, while the remaining four medical members were elected by the registered medical practitioners of Natal, forming one constituency. Of the original members of the first council only Dr. Archibald McKenzie and Dr. Campbell-Watt had had an unbroken record of thirty-two years' service on this body. One feature of the early days was the presence of the principal medical officer, which appointment was a survival of the old Medical Board; in 1909 the last of these officers left the council. The first president of the council had been Colonel James Hyslop, who had held the office for twenty-one years, during which Dr. Campbell-Watt was secretary; after Colonel Hyslop's death, in 1917, Dr. Campbell-Watt succeeded to the post of president, and the present secretary, Dr. Russell-Strapp, began his service in that capacity. Commenting on various aspects of the history of the Natal Medical Council, Dr. Campbell-Watt remarked that it was curious how the proverbial coach-and-four had been driven through the penal sections against unqualified practice, Natal having thus been a happy hunting-ground for the quack. Another curiosity was to be found in the amending Act of 1919, which permitted the South African student to proceed to any first-class medical or dental school in the world, and thereafter claim registration in South Africa on presentation of his diploma, irrespective of the fact that reciprocity of this kind was very rare. During the life of the Natal Medical Society it had given effect to the registration of 589 medical practitioners, 149 dentists, 655 trained nurses, 29 mental nurses, and 396 midwives. While registration was compulsory for medical practitioners and dentists, it was still only voluntary for nurses and midwives. The president remarked that, though delegates from the Natal Medical Council had co-operated with others in forming a consolidating Medical and Pharmacy Bill for the Union of South Africa in 1910, the fruits of this work had only just appeared; it had thus taken eighteen years to place a measure of this kind on the statute-book. In his final utterance as president, Dr. Campbell-Watt recalled the happy friendships which had made it easier for the Natal Medical Council to act up to the highest traditions of the medical profession, and expressed his conviction that the new Union Medical Council, as the supreme authority on medical ethics, would have a salutary and profound influence on the national welfare. The Natal Medical Council had fulfilled its destiny in the medical history of South Africa, and its successor would continue the work and traditions with a higher status, a wider horizon, and more extensive responsibilities.

Post-graduate Course, Capetown.

Under the auspices of the Cape Western Branch of the Medical Association of South Africa (British Medical Association), in co-operation with the medical faculty of the University of Capetown and the members of the staff of the New Somerset Hospital, a post-graduate course was held during January. The syllabus was arranged for the mornings only, but additional afternoon functions included a visit to the City Hospital for Infectious Diseases and to the Corporation Sewage Disposal Works at Athlone. On

January 11th an evening was spent at the new medical school buildings at Groote Schuur, which were thrown open for inspection. Clinical demonstrations in the departments of bacteriology, pathology, and chemical pathology were conducted by members of the university staff. On January 18th the course was brought to a conclusion by a meeting of the Cape Western Branch of the Medical Association of South Africa (British Medical Association), when a paper on the value of post-graduate instruction was read by Mr. E. Barnard Fuller. In the discussion that followed members who had attended the course expressed their appreciation of the facilities provided, and at the same time criticized certain features of the syllabus. The committee responsible for arranging the course regarded it as experimental to some extent, but there is little doubt that it was much appreciated by those who attended it, and that it served a definite purpose. It will almost certainly be repeated next year.

Hospital Policy in the Cape Peninsula.

At the beginning of 1927 the six hospitals controlled by the Cape Hospital Board—namely, Somerset Hospital, Woodstock Hospital, Rondebosch and Mowbray Cottage Hospital, Victoria Hospital (Wynberg), Simonstown-Kalk Bay Hospital, and the Peninsula Maternity Hospital—together accommodated 478 patients. The number of beds has since been increased to 536, and will shortly be further increased to 540. The daily units recorded at the six hospitals during 1927 were 161,394, compared with 174,024 during 1928, and the number of in-patients treated increased in the same period from 7,989 to 8,855. The total number of out-patients, which in 1927 was 116,943, rose in 1928 to 143,017. Similar increases are recorded in the board's two convalescent homes, where the number of persons dealt with rose from 642 to 714. In a comprehensive statement on the problem of augmenting the at present inadequate hospital accommodation, the board has outlined schemes for a new hospital on the Groote Schuur estate, the rebuilding of the Peninsula Maternity Hospital, an extension of the Woodstock Hospital and of the Victoria Hospital, Wynberg, and the conversion of a building at the Eaton Convalescent Home into a dormitory for non-European inmates. A considerable addition to the Cape-town Free Dispensary has been made possible by a bequest from the estate of the late Mr. Hiddingh. The position in regard to the district nursing service is interesting; in 1926 there were nine district nurses operating throughout the Cape peninsula; there are now twenty-two, and provision is being made for a further extension during 1929. A sister tutor has been appointed to the new Somerset Hospital, and the board will recommend the appointment of additional sisters to teach the probationers of the hospitals at Woodstock, Rondebosch, and Wynberg.

Medical Training for Natives.

At the European-Bantu Conference held in Capetown in February resolutions were passed urging the Government to adopt the recommendation of the Hospital Survey Committee of 1927 as the basis of a hospital programme for the needs of non-Europeans. This would involve the immediate provision of one bed for every 1,400 of the non-European population, the ratio within ten years to become 1 in 700. The need was impressed upon public health authorities for the establishment of easily accessible out-patient clinics for natives, and for the provision of an adequate ambulance service. The conference supported the recommendations of the Loram Committee that facilities be provided for the full medical training of non-Europeans in university courses, carrying the same entrance requirements and registrable qualifications as those applicable to Europeans. To defray the cost of training it was suggested that loans be made available for the assistance of deserving native medical students, and that pending the establishment of adequate facilities in South Africa a system of bursaries and loans be instituted to enable students to proceed overseas. Similar recommendations were made in relation to the training of non-European probationers in general nursing and in midwifery, and it was proposed that there should be a difference between the salaries of the registered nurse and of the unregistered. Chiefs, district councils, hospital boards, and municipalities were urged to provide careers and adequate remuneration for non-European nurses and health assistants. The conference welcomed the interest shown by the South African Council for Child Welfare in work among the non-Europeans, and recommended joint councils and other bodies to assist in the formation of welfare societies concerned with non-European children, and in the organization of health propaganda and instruction.

India.

Work of Indian Medical Schools.

In spite of financial handicaps progress is being made in developing the educational facilities at King Edward VII Memorial Hospital and the associated Seth Gordhandas Sunderdas Medical College in Bombay, which came into existence in 1925. In the annual report for the year 1927–28 it is stated that there were 50 fresh admissions to the College, bringing the total number of students at the end of the year to 139, of whom 6 were women students. For the Intermediate M.B., B.S. examination 57 candidates were presented at various times, of whom 28 passed. The first class of students admitted to the College appeared for Part I of the Final M.B., B.S. examination last September, and those who were successful will have qualified to take the second part at the end of the current year. Since the institution of the College considerable advance has been made in developing the various museums and in the equipment of the special departments, but it is regrettable to note that insufficiency of the resources available has prevented the anticipated expansion of research work. In one case certain investigations have had to be suspended. This side of the work of the College suffers also from the heavy demands made by the exigencies of teaching upon the time of the staff. At King George's Medical College, Lucknow, according to the report for 1927 of the inspector-general of civil hospitals for the United Provinces, there were 258 students at the end of the year, as against 243 the previous year. In the various examinations constituting Part I of the Final M.B., B.S. the number of students who appeared was 59, and the number of those successful was 34; in Part II the number appearing was 73, and the number of passes was again 34; in Part II of the First M.B., B.S. examination 36 candidates passed out of 56 who presented themselves. There was a decrease of 20, at 305, in the number of students under instruction at the medical school for men at Agra, and only 51 students passed the final examination as compared with 80 in 1926. The numbers of students on the roll at the women's school, 63, and the number of passes in the final examination, 7, were in each case one less than in the previous year. Such figures have something more than an academic interest, for they indicate the efforts being made to secure a high standard of medical training in India.

Financial Assistance for the Pasteur Institute.

The steady increase in the demands made on the Pasteur Institute at Kasauli has resulted in financial embarrassment, which is very gravely hindering its work. The popularity of antirabic treatment is now nearly three times what it was in 1910, and nearly twenty times that of 1901, when the Institute was opened. During 1926 more than 6,000 patients were dealt with, and over 2,000 others were to the local centres at Lahore, Rawalpindi, and Allahabad where vaccine is supplied by the Pasteur Institute. It has proved impossible to secure the necessary additional residential hospital accommodation, to keep the buildings in proper repair, and to provide up-to-date apparatus and equipment. An appeal for an increased grant was made in 1927 to the Government of India, which has now decided to accede to this request on the understanding that the additional liabilities so incurred shall be limited. The Government of the United Provinces has undertaken to contribute an additional sum of 10,000 rupees annually, and the Government of the Punjab has also agreed to make a recurring grant of 50,000 rupees during the year 1929–30, these donations being subject in both cases to the approval

of the legislative councils. A few Indian States have also promised to increase their contributions, but it is not thought that the amount available from this source will be large. It is generally realized that, should the Institute be compelled to close its doors for want of funds, the Government of India and other bodies benefiting at present by the services it renders would have to make separate provision for the antirabic treatment of patients from departments and areas directly administered by them, and also be obliged to undertake research.

Medical Service in Northern India in the Eighties.

Under the title of "Echoes of the past," Lieut.-Colonel G. H. Younge, R.A.M.C.(ret.), has contributed to the *Journal of the Royal Army Medical Corps* for January a description of a five-year tour of duty in the Bengal Presidency between forty and fifty years ago. Such a record must be of interest alike to the young officer who has just entered the service, to the older man who has done ten or twenty years' service, and has himself been through a somewhat similar tour of duty; most interesting of all to the contemporary who can look back on somewhat similar experiences of his own, nearly half a century ago. Much has changed during this period, and nowhere has change been more marked than in India. But to the man who went to India in the seventies or early eighties, Colonel Younge's account recalls memories long past and gone. *Forsan et haec olim meminisse juvabit.* Except for one unique experience, Colonel Younge's tour of service comprised the usual routine of duty, leave, sport, etc., which all young medical officers went through, and most of them probably enjoyed—ordinary hospital duty, cholera duty and cholera camps, marching in relief, travelling in charge of detachments, an artillery field firing camp, leave in the hills, at Masuri, and a six months' tour of hill duty, at Dalhousie. The author was stationed for considerable periods at Benares, Cawnpore, and Mecan Meer, and had the advantage, when moving in charge of detachments, of visiting many other places of interest—Calcutta, Lahore, Tiruzpur, Darjeeling. Of the great show places of Northern India, Cawnpore is the only one described, Agra and Delhi are not mentioned. His tour of duty, of course, began with the voyage to the East. And that voyage was an experience of a time long passed away, for he went out, as practically all officers then did, on one of the five famous old Indian transports, which were vessels of the Royal Navy, their ships' complements being all naval officers and men. He went out in the *Jumna*, and returned home in the *Serapis*, the latter the vessel in which King Edward VII, when Prince of Wales, made his journey to India. These transports disappeared from the Navy List some thirty years ago. Nowadays all trooping is done in hired transports of the mercantile marine, though for some years certain of the vessels of the Royal Indian Marine were used in this capacity. An interesting but unpleasant experience, which can have fallen to the lot of very few, was that of being present at the public execution of a British soldier. The criminal had "run amok," and had murdered several comrades. He was sentenced to be publicly hanged on the parade ground at Cawnpore, before the garrison of that station, and also in the presence of several other regiments which were halted there for the purpose, while on the march. This, we believe, was the last occasion on which such a public execution of a British soldier took place in India. It was the foundation of Kipling's poem of "Danny Deever." One of Colonel Younge's earliest duties was to go to Darjeeling in charge of a batch of invalids. The author states, "I longed to see Kinchinjunga, the highest peak of Mount Everest, but unfortunately during the whole of my stay it was hidden in a thick mist." During the rainy season, Kinchinjunga is often invisible from Darjeeling for days together, owing to mist. The view of the great ice and snow mass of Kinchinjunga, with its attendant smaller peaks, Paudine, etc., forty-seven miles only from Darjeeling, across a deep valley, must be one of the most magnificent views in the world. But Kinchinjunga (28,156 feet), splendid as its massive bulk is, has nothing to do with Everest (29,002 feet), a much higher and larger mountain, far to the west of Kinchinjunga, and not visible from Darjeeling.

Scotland.

Health of Scotland.

THE return of the Registrar-General for Scotland for the quarter ending December 31st, 1928, together with the supplementary return for that year, has just been published. The birth rate of the year was 19.8 per 1,000, and the marriage rate 6.7 per 1,000, both identical with the figures for 1927. The death rate was 13.3, as against 13.5 in 1927. This is the fourth successive year in which the death rate has been between 13 and 14 per 1,000. The birth rate, along with that of 1927, is the lowest yet recorded, the previous lowest being that of 1917, which was 20.3, as compared with the maximum Scottish birth rate, which occurred in the year 1876, and was 35.6 per 1,000, or 44 per cent. higher than it is now. The infant mortality of the year shows a decrease of 3, having fallen from 89 per 1,000 registered births to 86. The death rates from tuberculosis show reduction, that from all tuberculous disease having fallen from 100 per 100,000 to 97, and that of tuberculosis of the respiratory system having fallen from 71 per 100,000 to 68. Both of these rates are the lowest Scottish rates as yet recorded. Deaths from malignant disease numbered 6,902, a number which differs by only 17 from that of the previous year. The death rate for the fourth quarter of the year was 12.9 per 1,000, which is 0.8 less than that of the fourth quarter of 1927. With regard to the causes of death, of the 15,851 deaths registered in the quarter, 484, or 3.1 per cent., were attributable to the principal epidemic diseases, including 3 from enteric fever, 18 from measles, 37 from scarlet fever, 115 from whooping-cough, 119 from diphtheria, and 192 from diarrhoeal diseases among children less than 2 years old. In the counties, including burghs, the principal epidemic disease death rate ranged from 1.0 in Shetland to 0 in Berwick, Nairn, Orkney, and Peebles. In the larger burghs this death rate ranged from 0.8 in Hamilton, 0.5 in Glasgow, Motherwell, and Kilmarnock, to 0.2 in Edinburgh, Dunfermline, and Kirkcaldy, and 0.1 in Perth. Deaths from epidemic diseases other than those grouped as the principal epidemic diseases included 32 from cerebro-spinal meningitis, 32 from encephalitis lethargica, 41 from erysipelas, and 15 from acute poliomyelitis. Deaths from influenza during the quarter numbered 255, which constituted a death rate of 21 per 100,000. Deaths from malignant disease numbered 1,758 during the quarter, and constituted 11.1 per cent. of the total deaths. These numbered 76 fewer than in the fourth quarter of the previous year. Deaths from pneumonia, exclusive of influenza, numbered 1,458, equalling 9.2 per cent. of the total deaths of the quarter, but being 245 fewer than in the fourth quarter of the previous year.

Dinner to Sir James Leishman.

A complimentary dinner to Sir James Leishman on his retirement from the chairmanship of the Scottish Board of Health was held in Edinburgh on March 8th. Lord Provost Sir Alexander Stevenson presided, and the dinner was attended by about 160 persons, of whom the majority were associated with the work of the Department of Health for Scotland. Lord Alness proposed the health of the guest, and referred to the invaluable work which had been done by Sir James Leishman in connexion with the National Health Insurance Act and the Board of Health for Scotland. In his reply, Sir James Leishman said that it was a disturbing fact that the population of Scotland had remained practically stationary in recent years. He regarded with some perturbation the fact that the best of the population were leaving Scotland for the colonies and America. The cost of the social services of Scotland at the present time practically touched £1,000,000 per week, an amazing figure undreamt of by the older type of economist and statesman, and one calculated to give pause even to progressive men of all parties with reference to the capacity of the country to bear burdens. The annual health insurance income in Scotland amounted to about £4,000,000 from all sources, and up to three years ago the expenditure had been a good deal less. Although they

had built in Scotland some 89,000 State-aided and rate-aided houses, and were building 15,000 more, one of the real problems in the country still was bad housing, not only in the large cities, but in mining, agricultural, and highland areas. He thought that the Insurance Act had been a notable experiment in providing general practitioner treatment for the workers of the country, upon whom it had conferred a substantial benefit. The weakest part had been certification of sickness, but he would say no more on that point. One of the future problems was to bring together the municipalities and the voluntary hospitals in a good working arrangement.

Edinburgh Post-graduate Courses in Medicine.

The syllabus of post-graduate courses organized by a joint committee of the School of Medicine of the Royal Colleges and of the University of Edinburgh has just appeared. Since the first organization of post-graduate teaching in the Edinburgh Medical School in 1905, the courses which are offered to graduates have shown a great development both in number and in variety. A new feature of these courses consists in a course on clinical medicine, which will be given daily from 11 to 12 during the month of May by members of the medical staff of the Royal Infirmary, the fee being 3 guineas, while a course of instruction in medical side-room technique will be arranged if there are sufficient applicants. A similar course on clinical surgery will also be held from 11 to 12 for a period of six weeks by the members of the surgical staff of the Royal Infirmary, the fee being 3 guineas. During the summer vacation a four weeks' course in obstetrics, gynaecology, and diseases of children will be held from July 15th to August 10th, and will comprise clinical midwifery and gynaecology, obstetrical and gynaecological anatomy, physiology, and pathology, as well as child welfare and ante-natal clinics. The minimum number for which the course will be held is 12, the fee being 10 guineas. On its conclusion a four weeks' general practitioners' course will be held from August 11th to September 7th. This will include applied anatomy, clinical medicine, clinical surgery, clinics upon infectious diseases, gynaecology, diseases of children, diseases of the eye, diseases of the ear, nose, and throat, and dermatology. In addition, demonstrations will be given upon bacteriological diagnosis, morbid anatomy, insulin therapy, tuberculosis, radiology, ultra-violet ray therapy, dental treatment, and venereal diseases, in the afternoons. The fee is 10 guineas for four weeks, or 6 guineas for two weeks. Concurrently with the last, and at similar fees, a general surgical course will be held. This will include applied anatomy, general surgery, surgical operations, and clinics at the Royal Infirmary and the Royal Hospital for Sick Children, surgical pathology and physiology, venereal clinics, and radiology. The special departments of surgical diagnosis in renal disease, abdominal surgery, and gynaecological operations will also be dealt with. During the period of these courses special classes on vaccine therapy, medical chemistry, diseases of the blood, and radiology can be taken by those desiring to do so at a special fee. At other times of the year, during the academic terms, post-graduate classes can be attended dealing with tuberculosis, diseases of the nose, ear, and throat, ophthalmoscopy, venereal diseases, and surgical pathology. Various university classes, suitable for graduates, include medical entomology, diseases of tropical climates, psychology, bacteriology, neurology, chemical physiology, and applied anatomy. These are chiefly parts of courses of instruction for various university diplomas, but may be taken separately by any graduates interested in the subjects.

Glasgow Maternity Hospital.

At the annual meeting of the contributors to the Glasgow Royal Maternity and Women's Hospital, Sir John MacLeod, honorary treasurer to the institution, referred to the deficit on the year's working amounting to £4,000 on the ordinary accounts, which was £270 greater than the deficit of last year. This necessitated an encroachment on capital which could not go on indefinitely, as it would ultimately exhaust the capital fund. It was in the interest of the community at large that such an institution should receive greater public support, which he hoped would be forthcoming. Dr. Macfarlane said that the value of the social service which this hospital rendered to Glasgow was not fully understood by the entire community, which ought to take a greater interest in it. The Lord Provost said he considered that the Glasgow Maternity Hospital had a particular grievance in the fact that it was not treated by the Scottish authorities in the way that similar institutions were treated, and he thought that the Scottish Office might do more in answer to the representations which were made on behalf of the hospital.

Glasgow Eye Infirmary.

The annual meeting of the Glasgow Eye Infirmary was held on February 25th. Lord Provost Sir David Mason presided, and referred to the fact that this was one of the oldest philanthropic institutions in Glasgow, having been in existence for 105 years. It was interesting to note that in 1824 there had been 209 patients, that the 1,000 mark had been passed in 1851, and the 10,000 mark in 1883, the 20,000 in 1902, and the 30,000 mark in 1927. During the past year the number of out-patients had been 32,053, and the total attendances 72,562. The patients came not only from Glasgow and Scotland, but from various parts of England, as well as from the United States, the Transvaal, and British Guiana. The expenditure had exceeded the ordinary income, although there had been a gratifying increase in employees' subscriptions amounting to £192. He thought that it was scarcely fair to expect the citizens of Glasgow to bear the whole burden of the upkeep, and some scheme might be devised to appeal to likely sources beyond the limits of the city.

Glasgow Students and the Hospitals.

The special effort made by Glasgow students in January last on behalf of local hospital charities succeeded in raising the sum of £17,000. A meeting of the committee appointed by the Students' Representative Council for the purpose of allocating this sum was held on March 1st, and the following distribution was made. The Royal, Western, and Victoria Infirmaries, and the Royal Hospital for Sick Children and Maternity Hospital are each to receive £1,500 for the endowment of beds, while for ordinary purposes the Royal Infirmary is to receive £570, the Western Infirmary £425, the Victoria Infirmary £285, the Maternity Hospital £335, the Samaritan Hospital £300, the Ear, Nose and Throat Hospital £300, the Eye Infirmary £300, the Cancer Hospital £300, the Dental Hospital £500, the Elder Cottage Hospital and Lock Hospital £150, the Glasgow District Nursing Association, Ophthalmic Institution, and East Park Home £100 each. A grant was also made to the National Miners' Relief Fund of £2,975, and to the Lord Provost's Fund of £1,650.

Ayr County Hospital.

The report on the work of the Ayr County Hospital in 1928 presented at the annual meeting on February 25th showed that the number of patients treated in the wards during the year had been 1,773, of whom 1,467 were surgical and 306 medical. The ordinary income for the year had been £10,035, an increase of £835, while the total ordinary expenditure was £12,951. The total income from all sources had been £16,503, and the total expenditure £13,048, the credit balance being carried to maintenance reserve fund. The chairman, Colonel Houldsworth, thought that the financial position was satisfactory, because that of the voluntary hospitals in the country had been such in the post-war years to balance ordinary income with ordinary expenditure, and in this respect the county hospital had merely shared the common experience. Reference was made to the alarming number of cases arising from motor accidents, and the chairman said that many of those injured resided outside the hospital district and paid no contribution whatever for their treatment and maintenance in the hospital. He hoped that by some system of insurance, which would be compulsory upon the owners of motor cars, a solution would be found for this difficulty, as had been recommended by the Hospitals Association.

England and Wales.

Medical Society of London.

THE anniversary dinner of the Medical Society of London was held at the Trocadero on March 8th, with the president, Dr. John Walter Carr, in the chair. The toast of the society was proposed by Mr. Justice McCardie, who expressed appreciation of the good cheer always provided by doctors when they dined together, and of the habitual cheerfulness of doctors in the course of their daily work. The gathering that evening represented, he said, the things that united, rather than those that divided, the members of a calling. Sir Henry McCardie ended with a tribute to the great traditions of the medical profession and of this venerable society, now in its 157th year. The president, in his reply, drew an ingenious parallel between the Royal Society of Medicine and the Medical Society of London on the one hand, and the United States of America and Great Britain on the other. He then spoke of the opening up of the library and its development under the honorary librarian, Dr. A. F. Voelcker, and the registrar and secretary, Mr. Carter, and of the recent purchase, on advantageous terms, of the freehold of 11, Chandos Street. In the capable hands of Dr. Feiling and Mr. Davies-Colley, the honorary secretaries, the society was holding its own in all directions and "bringing forth fruit in old age." The health of the visitors was proposed by Mr. V. Warren Low, who recalled that Lettsom, their founder, delighted in hospitality, and that the society had done so ever since. Among the medical guests whom he welcomed with sparkling phrases were Sir John Rose Bradford, President of the Royal College of Physicians; Surgeon Vice-Admiral A. Gaskell, Medical Director-General, R.N.; Sir Ewen Maclean, President, and Dr. H. B. Brackenbury, Chairman of Council, of the British Medical Association; Colonel Samman, Master of the Apothecaries Society; the presidents of a number of sister societies; and the Editors of the *Lancet* and the *British Medical Journal*. Lord Riddell, in reply to the toast, declared his admiration for the medical profession and for the many-sidedness of so many of its members; he wondered what it was that made them speak so well, and what he himself had done to deserve the shafts of Mr. Warren Low's wit. Sir Ewen Maclean, who also responded, said that the Medical Society of London had amply justified its splendid detachment from the great amalgamation of 1907. Such medical bodies rightly left professional politics to the British Medical Association, which in the revolution of 1912 played its necessary part, and was now watching on behalf of the profession the new Local Government Bill. He asked for real and earnest help from individual members of the society in the shaping of this great measure along wise lines.

Cardiff Medical Students' Club: London Branch.

The London Branch of the Cardiff Medical Students' Club was inaugurated at a dinner on St. David's Day at Frascati's Restaurant, under the presidency of Dr. Dan Davies; some fifty former students of the Cardiff Medical School who are continuing their studies at various London hospitals owing to the closure to them of the Cardiff Royal Infirmary were present. The chairman, proposing the toast of "Dewi Sant," said that the study of the early history of the University of Wales, its struggles, and its successes, could not fail to deepen the patriotism of young Welshmen. Unlike other universities, which had owed much to benefactions from the rich, the University of Wales had been built up largely on the contributions of the peasantry. He felt sure that the breaking up of the federal University of Wales would be a retrograde step. Professor E. H. Kettle, who proposed the toast of "The Welsh National School of Medicine," expressed his firm faith in the future of the school, but feared that the ideals which had inspired those who had worked for the development of a great national institution had been replaced of late by pettiness of vision and selfish considerations. He hoped that the eclipse of the school would be only temporary, but its future recovery would need financial assistance from the Government; this was unlikely to be forthcoming unless there were substantial guarantees that the deplorable situation of last year would not recur. Mr. W. D. Lovelock-Jones, who seconded, expressed the sincere hope that Welsh nationalism would demand the resurrection of the school. Professor A. W. Sheen, in reply to the toast, said that negotiations were still in progress; he held out some hope that by next October the school might be re-established. Professor A. M. Kennedy also responded, and, though less optimistic, voiced his appreciation of the loyalty of the students in Cardiff to the professors. The toast of "The Cardiff Medical Students' Club" was proposed by Mr. J. P. G. Howells, and was seconded by Miss M. E. H. Jones. Professor T. Graham Brown, the president of the club, replied, and conveyed greetings from the junior students working in Cardiff. The health of "The Professors" was proposed by Mr. E. Llewellyn Williams and Mr. D. C. Harris, Professor E. C. Collis responding. Sir Ewen Maclean, who proposed the health of "The Guests," commented on the severity of the requirements of the University of London. The final toast of "The Chairman" was proposed by Mr. Lambert Rogers, and was accorded musical honours.

Leicester Medical Service.

The annual meeting of the Leicester Public Medical Service was held on March 5th, when the report of the board of management for the year 1928 was presented. It was stated that the continued depression in industry had had an adverse effect on the receipts, and the importance of increasing the number of subscribers was emphasized. The work in the various special departments for treatment had been continued, and the facilities thus provided had been welcomed by a large number of subscribers. Accommodation had been provided by arrangement with the Ministry of Health for the regional medical officer and the regional dental officer, as well as for the dental treatment of expectant mothers. A benefit fund established and maintained by donations from the trustees of the late Miss Sarah Barlow and the medical profession in Leicester, to enable uninsured people in straitened circumstances to purchase insulin at a greatly reduced cost, had proved very helpful in an increasing number of cases. The annual meeting of the Leicester subdivision of the Union of Medical Practitioners was held on the same day at the Central Dispensary. It was reported that the scheme for collective locumtenencies during holidays and sickness had proved of considerable value to the members. Donations to medical and allied charities, amounting to £113, were authorized by the committee during the year.

Gifts of Radium to the London Hospital.

Lord Knutsford informed the quarterly Court of Governors of the London Hospital on March 6th that two gifts, each of a gram of radium which cost £12,000, had been made to the hospital by two donors who insisted upon remaining anonymous. In addition, one of these had given £13,000 to be used as an endowment for a radium laboratory in which radium emanations could be collected in platinum containers for distribution. It was a condition of the gift that, if there was any excess of these emanations over that required for hospital cases, it should be available for members of the surgical staff for private patients, and also for treating cases of cancer in other hospitals. Assistants to work in the new laboratory were being trained by Professor Russ, head of the radium department at the Middlesex Hospital. Lord Knutsford explained that previously to receiving these gifts they had been endeavouring to treat nearly 1,000 cases of cancer a year, though they only had enough radium to deal with about 150. An additional endowment for the radium laboratory had been received from the East End Tradesmen's Association, and amounted to £1,800. Lord Knutsford expressed regret that the quinquennial appeal for £200,000 had only realized £118,337. It would soon be necessary to consider the question of enlarging the *x*-ray department, in which last year 25,000 radiographs had been taken.

Correspondence.

THE INTRACUTANEOUS TUBERCULIN TEST.

SIR,—I hope you will allow me space to reply to some of the points raised by Dr. Warwick Preston and Dr. Camac Wilkinson in your issue of March 9th (p. 475) in regard to my paper on intradermal tuberculin tests published in the *Journal* of February 23rd at page 336.

I am glad to be able to inform Dr. Camac Wilkinson that the tuberculin produced by Messrs. Burroughs Wellcome and Co. is quite as reliable as that of Meister Lucius and Bruning. This I have proved by carrying out simultaneous tests on the same persons with serial dilutions of both preparations, and finding the resulting reactions quite comparable up to the highest dilutions used. I elected to employ "old tuberculin" for the tests, because I had satisfied myself by long experience that it is one of the most reliable forms of tuberculin, and because it was important to work on lines comparable to those of another and far larger investigation now in progress in South Africa in order that the one series of observations might supplement the other. Further, it is to be noted that old tuberculin is the only tuberculin preparation recognized in this country for standardization under the Therapeutic Substances Act.

I need not remind Dr. Camac Wilkinson that the standardization of tuberculins, even when carried out on the most approved lines, still leaves much to be desired. It is difficult or impossible to make sure that one batch is of exactly the same strength as the next. The margin of error has been greatly reduced in recent times, but it has not yet been eliminated. For this reason it was necessary, in our investigation in Wales, to use the same batch of tuberculin throughout. This was rendered possible by the kindness of Dr. R. A. O'Brien, who was good enough to put aside a supply of batch No. 1154 for our special use.

On the question of a possible fallacy due to the presence of glycerin and toxic albumoses in the old tuberculin employed I am in a position to reassure Dr. Warwick Preston. Parallel tests were carried out, at the same time and on the same patients, with dilutions of a pure tuberculin protein free from glycerin and peptone, prepared by my colleague Dr. W. H. Tytler, and the results were strikingly similar. Again, Dr. Preston's fear that perhaps mere redness was taken as a "positive" is without foundation. A raised plaque of oedema, usually surrounded by a blush and sometimes showing a small bluish central area with a tendency to vesication—the "cocarde" of Mantoux—is the most typical reaction, but the essential is the raised and palpable plaque which must be sufficiently definite to be measured with the millimetre scale. My readings were carried out on the third day, the time of maximum reaction.

Reverting to Dr. Camac Wilkinson's remarks, the tests were not in any sense "casual observations made by a few juniors." Those on the healthy group, and some of those on the sick, were carried out by me personally. The rest were performed by members of the medical staff of the Welsh National Memorial Association, all of whom were whole-time tuberculosis experts possessing long experience of tuberculin, both in treatment and in diagnosis. Dr. Camac Wilkinson seems to think that it was a reproach to these investigators that the dilutions of tuberculin were made up by me and not left to them. I can assure him that all of them are quite familiar with the dilution of tuberculin for routine work; but, for an investigation on standard lines, standard methods are necessary, and slight personal idiosyncrasies are avoided by supplying the dilutions from a laboratory where the same technique is always employed. Again, it may be true, as Dr. Wilkinson thinks, that well-made dilutions of tuberculin keep indefinitely; but why chance it? We know that they keep without appreciable deterioration for three weeks or a month, and it is surely better to work on uniform lines within the limits of certainty.

Neither of your correspondents seems to have realized that my object was to compare the effects of varying strengths of *the same* tuberculin, not the effects of varying types of tuberculin in the same concentration. It is not surprising that there should be discrepancies between my results, obtained with a dilution of 1 in 1,000 of Burroughs Wellcome and Co.'s old tuberculin, read at three days, and those of Dr. Preston with 1 in 1,000 of T.A.F. of Meister Lucius and Co., read at the end of a week. What is more interesting is that Dr. Preston's findings confirm mine to the effect that his highest percentage of "positives" was in the non-pulmonary, and his lowest in the more severe pulmonary cases. He does not specify the exact composition of his "clinically free from tuberculosis" group. Mine consisted of healthy male adults residing in London. I have no doubt that a group of healthy persons could be found in which only 15 per cent. reacted, and there is no difficulty in finding such a group at any time amongst young children. I may say, however, that I have since tested another batch of adult non-tuberculous males, obtaining a slightly higher percentage of positives than that recorded in my paper. This finding is, in my opinion, the most important result so far gained from our Welsh investigation.

It is very necessary that the medical profession should realize that, so far as adults in this country are concerned, a positive tuberculin reaction has no diagnostic significance whatever. Medical men with less experience of tuberculosis than Dr. Preston and Dr. Wilkinson might, if this fact were not appreciated, diagnose a patient as tuberculous because of a marked positive tuberculin reaction, put him through a long and expensive course of tuberculin treatment, and finally announce the "cure" of a "pathological" condition which had never existed.—I am, etc.,

Cardiff, March 9th. S. LYLE CUMMINS.

TREATMENT OF EMPYEMA.

SIR,—There seems to me reasonable doubt as to the soundness of Dr. Stacey Wilson's respiratory dynamic published on March 2nd (p. 419). Probably the improvement in lung expansion after the operation for empyema, which he attributes to his method of inducing the patient to make expiratory efforts with a closed glottis, is really due to deep inspirations, and to the physiological effect of the contractions of the bronchioles during expiration. His patients' lungs expand for the same reason that the almost solid lung of the newborn infant expands after birth. How does he account for the baby's lung and all the alveoli becoming distended with air, for the baby's tidal respiration would only fill the trachea, bronchi, and bronchioles? But the dilatation of bronchioles in inspiration is followed by contraction, and so before all the first intake of air is expelled a fresh inspiration is made through the now widely opening bronchioles; once again the inspired air is obstructed in escape, and so the lung becomes more and more distended till all the alveoli are expanded, otherwise the child has areas of atelectasis.

Fortunately surgeons have discovered that a chest wall may be opened—as, for example, for a chronic empyema—and that, so long as the visceral pleura is not opened, the partially collapsed lung will not collapse more, but will even expand and come up to the opening in the chest wall, provided the expansile force *from within* is not too much hampered—as, for example, by greatly thickened pleura. I certainly do not suggest that expiration with a closed glottis may not be some additional help. It helps the baby when born—hence the value of crying lustily—but the glottic closure is only part of the all-essential similar and coincident contraction of the bronchioles. In fact, the effort to close the glottis involves concomitant bulbar impulses to the co-responding bronchiolar contractions.

One may ask, too, how Dr. Ramsbottom explains his case (*a*)—March 9th, p. 443—of pneumothorax following perforation of the *parietal* pleura by a hatpin; surely it must have been due to lesion of the *visceral* pleura, which is totally different in result in the matter of lung collapse.

The practical clinical import of these bronchiolar contractions during expiration has been insufficiently recognized. I drew attention to this question twenty-six years ago in a contribution to the *Bristol Medico-Chirurgical Journal* of March, 1903; I would gladly forward a reprint of this to anyone interested.—I am, etc.,

Bristol, March 9th. PATRICK WATSON-WILLIAMS.

A COLLEGE OF OBSTETRICS AND GYNAECOLOGY.

SIR,—In your article on the above subject (March 9th, p. 462) you state that you understand that the project has the approval of every professor of obstetrics and gynaecology in the United Kingdom. That may be so; but, as one who practised those branches of medicine for thirty-eight years, and was a professor for thirty-two, I should like to give some reasons for my disapproval.

Your article states that the proposed movement is made with the object of encouraging the study and improving the practice of obstetrics and gynaecology. There is an old-standing society still in existence for this purpose—namely, the Section of Obstetrics and Gynaecology in the Royal Society of Medicine. This Section includes nearly all the teachers of those subjects in this country, and is one of the finest schools for the above purposes in the world; no information is afforded as to the ways in which its object could be better achieved by a college. It appears to me that the improvement in teaching depends on the individual teachers, and not on the college of which they are members. The further objects of the proposed college—"advising in regard to technical training, instituting lectures and demonstrations, and diffusing information on all matters relating to this branch of practice by means of periodicals, books, or other publications"—are already carried out by the present Royal Colleges, the Royal Society of Medicine, and the special and general medical press. The "institution of a post-graduate diploma" and the seeking of authority "to co-operate, if invited, with existing bodies in the examination of candidates for qualifying diplomas" seem to point to a desire to compete with the present licensing bodies, or, alternatively, to grant licences of a higher grade, which would lower the value of the present degrees and diplomas. There seems no probability that the licensing bodies will give the required invitation to their competitors to provide examiners, whom the Royal Colleges have hitherto chosen from amongst the same obstetricians and gynaecologists as would form the Fellows of the new college. In that case the diplomas would be honorary and post-graduate, and the intention would seem to be to stamp the F.C.O.G. as an individual superior in the practice of obstetrics and gynaecology to the F.R.C.P. or F.R.C.S. This would be resented by the holders of those qualifications.

There is no doubt that general practitioners are responsible for a good deal of bad obstetrics and gynaecology; but the remedy seems to be for the specialists to show that they do better work, and not to bemuse themselves with the idea that a new set of capital characters can be as easily attached to a man's work as appended to his name. The present movement is due to the neglect of obstetrics and gynaecology by the Royal Colleges. The Royal College of Physicians instituted a special diploma in 1783, and has conferred its Fellowship on a number of its obstetrical and gynaecological members; but it cannot be said—although Harvey, Blundell, Denman, Matthews Duncan, and others received that honour—that, in recent years, the Fellowship has been conferred as freely as on its medical members, or as the importance of the subject and the character of its practitioners deserved. An improvement in this respect is overdue, and would be welcomed, I think, by many Fellows who are not specialists. But to form a new college, which could not, at least for many years, compete in tradition, buildings, library, or funds with the existing Royal Colleges, would be to place obstetrics and gynaecology in a position of inferiority which its importance and achievements do not deserve. Far better would it be to extend the conjoint work of the two Royal Colleges by a complete amalgamation, as Clifford Allbutt suggested, into a Royal Academy of Medicine.—I am, etc.,

HERBERT R. SPENCER, M.D., F.R.C.P.

London, W.1, March 9th.

COLLES'S FRACTURE.

SIR,—In your issue of March 9th (p. 477) Mr. Cochrane expresses the view that the real cause of disablement after Colles's fracture lies in "neglect to reduce the forward luxation of the lower end of the ulna so frequently present," and calls attention to the fact that this was not explained in our article on fractures of the lower end of the radius, which appeared in the *British Medical Journal* of January 12th.

The reason of the omission is not far to seek. We are not familiar with forward luxation of the ulna in association with *Colles's fracture*. We regard the ulna as the fixed bone in relation to which the lower fragment of the broken radius suffers a variety of displacements. Even if Mr. Cochrane's description is interpreted as backward subluxation of the lower radial fragment upon the ulna, we still maintain that such is a rare accompaniment of this type of fracture. We have encountered the condition in not more than three cases in the last five years. The radial fragment when it is forced directly backwards in the shock of the impact, rotates around the ulna, the movement taking place at the lower radio-ulnar joint, and resembling the act of normal supination. In the most severe cases of backward displacement of the lower radial fragment it is conceded that such a subluxation may occur, but certainly no case of failure reported in the article to which Mr. Cochrane refers can be attributed to it.

Varying degrees of subluxation at the inferior radio-ulnar joint certainly do occur, however, in Colles's fracture, but in no sense can the subluxation be regarded as a forward luxation of the ulna. We refer to the altered relation of the articular surfaces of this joint caused by *backward tilt* of the lower fragment of the radius, which is the most *constant displacement of Colles's fracture*. The *utmost* care must be taken fully to reduce this displacement, so that the lower articular surface of the radius faces downwards and slightly forwards, a point upon which very great stress was laid in the article mentioned above. If full correction of this backward tilt is obtained, subluxation at the inferior radio-ulnar joint is reduced automatically.—We are, etc.,

HAROLD EDWARDS,
E. BELLIS CLAYTON.

London, W.1, March 11th.

PROGNOSIS IN ECLAMPSIA AND ALBUMINURIA OF PREGNANCY.

SIR,—Dr. James Young, in his letter of your issue of March 2nd (p. 419), brings forward further evidence in favour of his contentions. This is all to the good, and justifies the concluding paragraph of my first letter (February 16th, p. 320) that criticism would be helpful. For the moment this new evidence must be left for consideration before its ultimate importance and weight can be assayed in the subject under discussion. What I must evidently repeat is that at present no "positive" and "conclusive" evidence exists—words deliberately and intentionally chosen—that the kidneys are previously "healthy," using that word in its broadest sense, before the initial attack of toxæmia. What would Dr. Young call evidence based on the examination of the renal ability or disability of a large series of women before the first pregnancy and the result tabulated with the results and complications of their subsequent pregnancies? In comparison, his fresh evidence, though important (as every possible link is important in obscure problems under investigation), is evidence by inference only, if I may so describe it; the hypothetical investigation mentioned above may well be, in the present state of medicine and society, impossible, but I can assure Dr. Young that some, if only in a small way, are slowly collecting such evidence.

With regard to Dr. Young's remarks in the second paragraph of his letter, careful re-reading of my letter will show that I (quite intentionally) refrained from expressing personal "views." What I pointed out was that other workers had emphasized the difficulty in distinguishing "*nephritic*" from "toxic" cases, even with elaborate biochemical investigations. It is hardly an answer to reiterate that these workers have confused the issue in holding there are two conditions, not one. That is just the point I think where the views diverge.

Grateful, Sir, as I am for the room you have found for this correspondence, I am aware that the whole subject is so technical and one mainly for experts that I feel it would be more suitable for discussion in the columns of a paper devoted entirely to obstetrics, and having reason to

know that these questions will be examined and discussed elsewhere in a not far distant future, perhaps I may leave it at that.—I am, etc.,

Norwich, March 4th. ARTHUR CROOK.

MINOR ORTHOPAEDICS IN GENERAL PRACTICE.

SIR,—It gave me great pleasure as I read Professor John Fraser's address in the *British Medical Journal* of March 2nd (p. 383) to feel that I, a general practitioner, was so much in agreement with one in authority. With one statement alone did I not agree. Professor Fraser says a hallux valgus of any degree is almost invariably accompanied by flat-foot, and the *cause* in the majority of cases is flat-foot. Certainly half—I believe more than half—the cases of hallux valgus I have seen have not been accompanied by flat-foot. I know three middle-aged sisters each of whom has well-marked hallux valgus, and each has well-arched feet. Another patient, an elderly lady, with severe hallux valgus and a hammer-toe, had a well-arched foot.

I believe the commonest cause of hallux valgus to be the wearing of shoes with high heels and toes pointed out too far. I mean when the shoes are placed side by side the medial line of the foot (inside the shoe) traced forwards from the heel is turned outwards at the metatarso-phalangeal joint of the great toe. The foot is thus placed in the position of hallux valgus, and the high heels cause the weight of the body to press the feet more firmly into this incorrect shape. In support of the second part of this theory is the fact that the great majority of cases occur in women, even though men use equally badly shaped footwear.

But what disappointed me in Professor Fraser's address was that, after hinting that the cause of several of these distressing conditions of the feet lay in faulty footwear, he did not denounce the manufacturers of boots and shoes who give so much discomfort—and often anguish—to the wearers, and so much unnecessary labour to the consulting surgeon.

In relation to the prevailing shape of footwear I should like to point out the following facts:

1. When a baby's feet are placed side by side so that the heels and great-toe joints touch, then the great toes lie parallel and touch throughout their length. The same applies to the feet of a savage, whose feet are always bare. But I know of no place where shoes of this shape are obtainable ready-made for adults. From the metatarso-phalangeal joint the medial lines of all shoes and boots turn away from one another so that the contained great toes cannot lie parallel, but are forced apart to enclose a considerable angle between them.

2. A neat shoe can be made of anatomically correct shape, the only difference being that, when placed side by side, the feet would lose the appearance of being turned out, which the present shoe gives.

3. When I have approached those who sell shoes and discussed this point with them they say that a neat shoe of the desired shape can easily be made, but that no adult has a foot of that shape. That this is so I can affirm. I have never seen an adult accustomed to wearing boots or shoes who can place the feet side by side and show the great toes lying parallel. There is, however, hope for the coming generation if those in authority will denounce the modern shoe and direct the shoe manufacturers in the way they should go. I believe they are quite ready to listen.

—I am, etc.,

R. A. MURRAY SCOTT, M.B., B.Chir.Cantab.

Leeds, March 4th.

CEREBRAL ANGIOSPASM.

SIR,—Recent correspondence regarding cerebral angiospasm prompts me to draw attention to an article on this subject (*British Medical Journal*, May 16th, 1914) by Professor William Russell of Edinburgh, which was reprinted in his book *The Sphygmometer: Its Value in Practical Medicine* (Baillière, Tindall and Cox, 1921). Anyone who is interested in this phenomenon will derive a good deal of benefit from the perusal of this article.

In my experience cerebral angiospasm is by no means uncommon. I have a patient whom I have observed for more than seven years, a man over 70 years of age, who has had numerous attacks. He is now so well schooled in the premonitory symptoms that he can prevent an attack by taking 1/4 grain of erythrol tetranitrate. In the many attacks during which I have seen him he has suffered from hemiplegia and loss of speech. These have invariably passed off quickly following 1/2 grain of erythrol tetranitrate. Phenacetin I have found equally useful.

I feel perfectly sure that it lies within the power of anyone to prevent in these subjects such a disastrous consequence as cerebral softening, if only the varied manifestations of cerebral angiospasm are kept in mind.—I am, etc.,

P. H. J. TURTON, M.D.Ed.

Heanor, nr. Nottingham, March 9th.

SIR,—I have notes on a case diagnosed as cerebral angiospasm which I saw in 1922. A man, aged 56, woke up one morning early with a feeling of oppression; he was confused and hemiplegic. The paralysis passed off in twelve hours, but returned in twenty-four hours; a few hours later it again disappeared but recurred and passed off as quickly, save for a slight dragging of one foot. The urine was normal, and so, apparently, was the heart. The blood pressure was 300; it was tested several times and treatment reduced it to 230 mm. The patient kept well for eighteen months; then one morning while shaving he had precordial pain, returned to bed, and sent for me. I was auscultating the heart when I heard its beats cease. Mistrusting my ears I looked up at his face; he was dead.—I am, etc.,

Darlington, March 5th. W. W. FORSYTH, M.B.

VACCINATION IN THE LIGHT OF RECENT EXPERIENCE.

SIR,—It would be of very great interest to the average medical officer of health if some authoritative pronouncement could be made on the relation between alastrim and small-pox. If they really are two distinct diseases, how are they to be distinguished? The question is of vital importance if the subject of vaccination is raised. Is it worth while going to the trouble of searching out and following up contacts, and insisting on vaccination, for a disease which, according to some authorities, is merely like a mild chicken-pox? In the second place, why vaccinate a contact and thereby almost certainly prevent him from working for a number of days, when this measure is to protect him against risk of infection by a disease so mild as not to be worth worrying about?

But are there two diseases? Obviously the Ministry of Health does not think so, or it would not require such stringent regulations carried out. Furthermore, is it always possible to say definitely that one is dealing with alastrim or with small-pox? Alastrim, it is said, does not kill; neither does mild scarlet fever, but it is quite capable of infecting another child so that a fatal result ensues.

Surely alastrim is only mild small-pox, and it does not breed true, despite Dr. R. P. Garrow and others. In Yorkshire in 1927 I had an outbreak of small-pox in which the initial cases were so slight that some patients had not even called in a doctor; yet these cases infected others, one girl so severely that the medical superintendent of the hospital to which she was admitted, a man of much experience, anticipated her death. She eventually recovered, but for a time her eyesight was in danger. Needless to say, her rash was typical of small-pox. Doubtless I shall be told that the first cases, though mild, were really true small-pox; but how is one to know that in the first place?

There is another side to the picture. Last year I was called to the union infirmary to examine a tramp with a severe attack of typical small-pox; his face was covered with confluent or semi-confluent pustules. He was delirious, his pulse was poor, and he was pulled through only by dint of careful nursing. But in due course certain of his contacts at a common lodging house developed small-pox; all of these were quite unprotected by vaccination; yet their only symptoms were a few spots, with practically no malaise or discomfort at all. Indeed, had it not been for the first case, and the fact that they were being inspected daily, I am confident that their disease would not have been recognized, for no one would have seen it.

In view of the above facts, what is one to think except (1) that small-pox, like scarlet fever, affects some severely and others mildly; (2) that it appears sometimes in severe epidemics and sometimes in epidemics of the type generally prevalent to-day; and (3) that the types—that is, mild (alastrim) and severe (small-pox)—do not breed true to type, but true to disease, of which there is one?

In view of the fact that we do not know how each individual will be attacked by the disease, we still advise vaccination in epidemic times and safeguard our contacts as well as we can. Thus do we endeavour to limit the spread of the disease, which, though mild to many at the present time, is severe to the few. Unfortunately we do not know which the few will be, nor do we know even how long the present mild type will persist.—I am, etc.,

F. A. BELAM, M.D., D.P.H.,
M.O.H. Guildford.

March 4th.

PYORRHOEA ALVEOLARIS.

SIR,—I write to endorse the remarks of Mr. J. H. Badcock on February 23rd (p. 373) with reference to the value of the regular use of the toothbrush in oral hygiene.

Some few months ago I was asked to undertake the duties of part-time regional dental officer. A large percentage of the patients I have seen are "working" folk of middle age, to whom the use of the toothbrush has been unknown from one year's end to the other. Suffering from digestive troubles, they have been referred by their medical man to their dentist, and he has marked their mouths for a wholesale clearance of the teeth. An oral examination in every case reveals a similar state of things—a more or less complete set of teeth, discoloured and unutterably dirty, with considerable deposits of "tartar" in each jaw, and a general septic gingivitis and alveolar absorption. As a consequence the teeth, though often free from caries, are loose, and owing to their unwholesome condition worse than useless for the purposes of mastication. Without doubt pyorrhoea alveolaris in such cases is a dirt disease, and preventable, and one never sees, as I know from over thirty years' experience in private practice, such a state of things in the mouths of people with whom the intelligent use of the toothbrush has been a matter of daily routine.

The truth is that there are millions of people in this country who to-day are ignorant of the fact that daily cleansing of the mouth can affect their health one way or the other. In the present generation this continued neglect has done its work, but if the boys and girls of the working classes can only be induced to understand the necessity of a clean mouth, the daily use of the toothbrush would make such cases as I have described relics of an age which forgot to brush its teeth.—I am, etc.,

F. C. PORTER.

Nottingham, Feb. 27th.

The Services.

HONORARY SURGEON TO THE KING.

COLONEL F. G. PROUDFOOT, T.D., Assistant Director of Medical Services, 48th (South Midland) Division, Territorial Army, has been appointed Honorary Surgeon to His Majesty the King, with effect from February 16th last.

DEATHS IN THE SERVICES.

Surgeon Lieut.-Colonel William Michael Courtney, *Bengal* Medical Service (ret.), died on December 2nd, 1928, aged 83. He was born on September 29th, 1845, the son of Patrick Courtney, Esq., of Drogheda, was educated at the Ledwich school of medicine in Dublin, and took the L.R.C.S.I. and L.A.H. in 1868. Entering the I.M.S. as assistant surgeon on October 1st, 1869, he became surgeon major after twelve years' service, and surgeon lieutenant-colonel when that rank was instituted in 1891, retiring on December 7th, 1895. He spent his whole service in military employment, and served on the north-east frontier of India in the Daphla campaign of 1873-74; in Burma in 1886-87, gaining the medal and clasp; and in the Chin Lushai campaign of 1889-90, receiving a clasp.

Lieut.-Colonel Phirozsha Jamsetji Damania, Bombay Medical Service (ret.), died on December 15th, 1928, aged 77. He was born on August 29th, 1851, was educated at the Grant Medical College, Bombay, where he took the L.M.S. in 1876, and, after coming to England, the L.S.A. in 1877 and the L.R.C.S.Ed. in 1878. He entered the I.M.S. as surgeon on March 30th, 1878, attained the rank of lieutenant-colonel after twenty years' service, and retired on October 28th, 1893. He served in the Afghan war in 1880-81, receiving the medal, and in Burma in 1885-87, gaining the medal with a clasp.

Lieut.-Colonel Cecil Edward Bulteel, Indian Medical Service, died on December 20th, 1928, aged 51. He was born on August 17th, 1877, was educated at King's College, London, and took the M.R.C.S., L.R.C.P.Lond. in 1901. Entering the I.M.S. as lieutenant on September 1st, 1902, he became lieutenant-colonel on March 1st, 1922. His service had been spent in military employ, and his last appointment was the command of the Indian military hospital at Belgaum. He served on the north-west frontier of India and in Afghanistan in the third Afghan war in 1920-21, was mentioned in dispatches in the *London Gazette* of August 3rd, 1920, and received the O.B.E. on January 1st, 1920.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE John Lucas Walker studentship of £300 a year for original research in pathology has been awarded to Neil E. Goldsworthy, Ph.D., for three years.

At a congregation held on March 9th the following medical degrees were conferred:

M.B., B.CHIR.—G. W. Pimblett, R. G. Apthorpe.
M.B.—W. E. Underwood.
B.CHIR.—E. A. E. Palmer.

Congregations will be held next term on April 26th, May 11th and 24th, and June 8th, 15th, and 18th.

UNIVERSITY OF LONDON.

THE Senate at its meeting on February 20th resolved:

(1) That the Department of Hygiene and Public Health at University College be closed on July 31st, 1929, and that the work for the Diploma in Public Health and for post-graduate and research students in hygiene hitherto carried on in that department, in conjunction with that in bacteriology carried on in the University College Hospital Medical School for candidates for the Diploma in Public Health, be transferred as from the same date to the London School of Hygiene and Tropical Medicine.

(2) That the teaching of epidemiology and vital statistics for the Diploma in Public Health be transferred to the London School of [illegible] as from August 1st, 1929.

[illegible] direction of research in epidemiology [illegible] for the Diploma in Public Health, at present undertaken by a Reader at University College, be continued in the Department of Applied Statistics and Eugenics at University College.

(4) That [illegible] University College [illegible] be known as "The D[illegible]"

Candidates for the degree of Ph.D., which is to be instituted in non-clinical subjects for internal students in the Faculty of Medicine, will be required to hold, in a branch of study akin to that in which they propose to proceed to the Ph.D. degree, the degree of M.B., B.S., or B.D.S., or B.Pharm. The regulations for the Ph.D. degree are to be amended accordingly.

The ceremony of Presentation Day will be held in the Albert Hall on Wednesday, May 8th, at 2.30 p.m., and the graduation dinner will take place at 8 p.m. on the same day in the Merchant Taylors' Hall, Threadneedle Street, E.C.

A course of lectures on mental deficiency, supplemented by a course of clinical instruction, will be held from May 27th to June 1st. A course, mainly for those of the school medical service, for the purpose of studying exceptional conditions allied to mental deficiency, will be held from June 3rd to 8th. Full particulars may be obtained on application to Miss Evelyn Fox, care of the University Extension Department, University of London, S.W.7.

Applications for grants from the Dixon Fund for assisting scientific investigations must be sent in between April 1st and May 15th, accompanied by the names and addresses of not more than two persons to whom reference may be made. Full particulars may be obtained from the Academic Registrar.

UNIVERSITY COLLEGE.

A Bayliss-Starling Scholarship of about £120 for physiology and biochemistry will be awarded by the University College Committee in June next. Candidates must submit, on or about May 15th, to the Secretary of University College, London, a statement giving full particulars of his educational career and of his qualifications for entering on a course of training in the principles and methods of research.

UNIVERSITY OF MANCHESTER.

THE Council and Senate adopted a resolution on March 5th asking the University Court to authorize conferment of the degree of Doctor of Science (*honoris causa*) upon Sir Ronald Ross, K.C.B., M.D., F.R.S., in recognition of his great work in the prevention of malaria. It is proposed to confer the degree on Founders' Day, May 15th, two days after Sir Ronald Ross's seventy-second birthday.

UNIVERSITY OF SHEFFIELD.

MR. VINCENT TOWNROW, F.R.C.S., has been appointed lecturer in diseases of the ear, nose, and throat, and Dr. Rupert Hallam lecturer in dermatology.

Obituary.

CLEMENS PIRQUET, M.D.,

Professor of Paediatrics in the University of Vienna.

THE medical profession has lost one of its most notable members by the tragic death of Freiherr Clemens Pirquet.

Clemens von Pirquet was born in Vienna in 1874, and in that city he has died, leaving behind him, as a memorial of his indefatigable work in the cause of the children, the Children's Hospital and Clinic attached to the University of Vienna, in the development of which he played such a prominent part. He was educated at Kalksburg, and later in the Universities of Vienna and Graz, obtaining the M.D.Graz in 1900. For some years after this he acted as assistant to Professor Escherich, and in 1908 became professor of paediatrics at the Johns Hopkins University at Baltimore. After two years he returned to Europe, and, first at Breslau and later at Vienna, he built up for himself a world-wide reputation. Immediately after the war Pirquet, who had now discarded the "von," threw himself whole-heartedly into co-operating with various agencies which sought to succour the children of Austria. With an amazing administrative ability and grasp of detail he combined an immense knowledge of the scientific aspects of nutrition, so that he was able to advise as to the best methods of distributing food and money down to the last crumb and farthing. Then followed the acceptance of an invitation to return to America, but, once across the Atlantic, nostalgia set in, and Pirquet returned to Vienna to the clinic to which all students of paediatrics have felt themselves drawn at one time or another.

Of Pirquet's contributions to medical science the cutaneous tuberculin reaction which bears his name is known to a wide circle, but although of great value in illustrating the clinical conception of allergy which he introduced, and demonstrating the wide distribution of tuberculous infection, this represents to a more limited section of the scientific world only a very small part of his labours. His work on the assessment of the state of nutrition of children by measurement of the weight and sitting height, the mathematical formulae devised to express an "index of nutrition," and the correlation of this with the dietetic requirements as illustrated by his "nem" system, was the most important piece of collected and sustained research for which Pirquet was responsible; and for this he will be most gratefully remembered by posterity. This system of nutrition was by no means easy to follow, as was indicated by the reviewer of a second edition of a work by Pirquet and his associates on the nutrition of healthy and sick children, mentioned in these columns last year (May 19th, p. 851), but no one belittled the sound basis of Pirquet's views on human nutrition, and he had abundant opportunity for the practical application of his ideas during the starvation period in Vienna. His "Pelidisi" system for estimating and recording the state of nutrition of children by observation of the skin, muscle tone, etc., was an extension of the sitting height and weight formula; again, while not easy to follow, especially in some of its clinico-mathematical conceptions, the system was essentially scientific, and has formed a basis for many inferior systems in other parts of the world.

Pirquet's work and writings have had considerable influence on paediatrists, especially of the German- and English-speaking races during the pre-war years, and his stimulating presence and gracious manner will now be sadly missing from the Vienna school. Many of those for whom the opportunity of visiting Pirquet there had not yet arrived were looking forward to hearing him open a discussion on the prevention and cure of tuberculosis in early childhood at the Annual Meeting of the British Medical Association in Manchester this year, and their disappointment will be keen. The children of the world have lost a great friend—he was president of the Union Internationale de Secours aux Enfants—the medical profession has lost a great leader, and the Austrian nation a cultured nobleman who loved his people dearly and served them well

DR. CHARLES PAGET LAPAGE, president of the Section of Diseases of Children at this year's Annual Meeting of the British Medical Association in Manchester, sends the following appreciation: The untimely death of Professor Clemens von Pirquet is a very great loss. Only his own country, which has benefited so much by his work, can estimate fully the greatness of that loss, but those of us who knew the value to paediatrics of his initiative and energy and clear thinking feel that we have lost a leader and a great man. He was coming to Manchester in July to open a discussion in the Section of Diseases of Children on tuberculosis in infancy and early childhood: its prevention, diagnosis, and cure. In a letter on January 21st he keenly discussed all the arrangements for this meeting, and concluded, "Looking forward to see this part of England." We in Manchester, therefore, feel a keen sense of personal loss that death has deprived us of the opportunity of meeting and hearing this outstanding physician.

CLIVE RIVIERE, M.D., F.R.C.P.,

Physician to the City of London Hospital for Diseases of the Chest and to the East London Hospital for Children.

THE death of Clive Riviere is an irreparable loss, not only to the Chest Hospital, which he served so well, and to all his friends, but to progressive medicine. He inspired confidence, admiration, and affection in all who knew him: confidence in his judgement, admiration for his skill and character, affection for his gentle and unselfish disposition. He was ever thoughtful and considerate for others. He was devoid of all pettiness, and any feelings of jealousy were entirely foreign to him. With a mind of great originality was combined a high order of technical skill, and it was a delight to watch his work. His sensitiveness to suffering in others served as a constant stimulus to him to aim at its relief, and he was continually thinking over and devising new ways to alleviate or to cure conditions that were regarded as hopeless. Of a family of artists, he was himself an artist. He was a man of wide interests and culture, fond of music and reading, loving the beauty of simple things, the countryside, and the sunshine. With all his qualities of greatness, with a world-wide reputation that his work and his writings had justly given him, he was the most shy, the most humble-minded and modest of men. In him we have lost one who was indeed the very pattern of an English gentleman and a great physician, who was at once a master and a friend.

He was born in 1872 at Charlton Kings in Gloucestershire, son of Briton Riviere, R.A. His mother was a daughter of John Dobell and a sister of Sydney Dobell. He was first educated at St. Andrews University. It may surprise those who knew him to learn that there he distinguished himself at golf. In fact, he was excellent at all games demanding quickness of eye and delicacy of touch. He rarely played them, however, and never in his later years, as he found life too full to spare time for games. These faculties, however, combined with an artistic sense and a very musical ear, undoubtedly helped him to achieve eminence in his particular branch of medicine. After St. Andrews he was sent to University College School, and thence to University College. He began his professional training at St. Bartholomew's, where he gained the Brackenbury Scholarship and became house-physician, casualty physician, and demonstrator of pathology. He was qualified in 1898, when he obtained the M.B. of London University. In 1900 he gained the M.D. and the M.R.C.P., and in 1909 the Fellowship of the Royal College of Physicians. While at St. Bartholomew's he began to take a special interest in affections of the chest, one of his earlier papers being "X-ray tuberculous fibrosis in children," which appeared in the *St. Bartholomew's Hospital Reports*. After a period at Tübingen University he became registrar at Great Ormond Street, then physician to the Shadwell Hospital for Children, from which he resigned in 1928, and was physician to the City of London Hospital for Diseases of the Chest, Victoria Park, where he was actively engaged in progressive work until the time of his death. He

here that he did the work that gained for him a world-wide reputation. He was one of the pioneers of artificial pneumothorax treatment in this country, and he lived to see a general adoption of this wonderful method which he championed through many years of neglect. His book on the subject is classic. His next most valuable contributions to medicine were his insistence and instruction on the early diagnosis of pulmonary tuberculosis, which he rightly held to be of such vital importance in successful treatment, and his work on the development of the surgery of the chest. His teachings on the former are incorporated in his book *The Early Diagnosis of Tubercle*, a masterpiece of lucidity and breadth of view, qualities which characterize all his writings.

It is a tragedy that his work was cut short at a time when great advance is being made in thoracic surgery, in which he would have continued to take an important and progressive part. He was for ever devising new and improved methods, and at the time of his death was working out a new operation for apical collapse to take the place of the present unsatisfactory measures for apicolysis. Among other achievements must be mentioned his writings on tuberculin treatment and bronchiectasis. Although a physician to a children's hospital, he was not so well known in this respect. Many cases, however, of tuberculosis in young children gravitated to him, and he was greatly interested in them. Children at once took to him and loved him.

His last act was one of characteristic devotion to duty. Feeling far from well, he went, on a bitterly cold evening, to see a nurse at the hospital who was desperately ill with pneumonia. He came back, and in a few hours had a rigor. Pneumonia set in, and was accompanied by a most painful diaphragmatic pleurisy. After four days he was much better, but on the fifth night a pneumonic area on the other side spread rapidly, and he was overwhelmed by it and died the following afternoon of heart failure.

F. G. C.

Dr. ROBERT HUTCHISON writes: By the sudden and untimely death of Clive Riviere the profession has lost a man of a type that can ill be spared. He might be described as being in the best sense of the word a gentleman, and he will be held in remembrance more for what he was than for what he did. Modest, kindly, and courteous, he was truly one who envied not, vaunted not himself, was not puffed up. He loved all beautiful things and hated everything ugly, mean, or pretentious, and his many friends will always be grateful for the example of a character of so much charm. Their sympathy will also go out in full measure to her who shared with him twenty-three years of singularly happy married life, and who was always his chief friend and companion.

ROWLAND HILL COOMBS, M.D., M.R.C.P.,

Consulting Physician to the Bedford County Hospital.

WE regret to record the death, at the age of 84, of Dr. R. H. Coombs, which took place at his home in Bedford on March 3rd.

Rowland Hill Coombs, eldest son of Dr. James Coombs, was born at Bedford, receiving his early education first at the Modern School and afterwards at Bedford School. In 1862 he entered as a student at St. Bartholomew's Hospital, qualifying L.S.A. and M.R.C.S. in 1866, and L.R.C.P. in 1867. In 1884 he graduated M.D.Durham. In 1922, being then in his seventy-eighth year, he passed the examination for Membership of the Royal College of Physicians of London; probably he was the oldest candidate who ever sat for that examination. For more than fifty years Dr. Coombs was physician to the Bedford County Hospital, and at his jubilee presentations were made to him by the staff, and he was entertained to dinner by the medical men of Bedford. For many years he was surgeon to the Bedfordshire Militia and lieutenant-colonel in the Royal Militia Staff Corps; later, when the Militia was incorporated into the Special Reserve, he held the rank of surgeon lieutenant-colonel in the Bedfordshire Regiment. Among his other medical appointments were those of medical officer to Elstow School and medical officer to the Isolation Hospital of the Bedford Rural District Council. Some years ago he retired from private practice, but continued to carry on the duties of his public appointments till a few days before his death.

Dr. Coombs played an important part in the public life of Bedford. He was the oldest justice of the peace for the borough, his appointment dating from 1894, a trustee of St. John's Hospital and of the Bedford Municipal Charities, and a former director of the House of Industry. In 1909 he became Deputy Lieutenant of the County, an office he held until his death. As long as he could he attended the bench and carried out his duties as magistrate.

During the greater part of his professional life Rowland Coombs was an active member of the British Medical Association. He held office as president of the South Midland Branch in 1894; from 1901 to 1903 he was a member of the South Midland Branch Council. From 1904 to 1906 he was on the executive committee of the Bedford and Hertfordshire Division, and acted as its representative at the Annual Representative Meetings from 1904 to 1912. In 1910–11 he represented the Territorial Services on the Naval and Military Committee of the Association. He is survived by a son—Dr. H. M. Coombs, who practises in Bedford—and by three daughters.

News has been received of the death of Dr. CHARLES M. EKINS at Alexandria on February 10th. Son of the late Major-General Ekins of the Indian Army, Charles Ekins studied medicine at University College Hospital, qualifying M.R.C.S., L.R.C.P. in 1900. During his student days he was a prominent Rugby footballer. After serving as a civil surgeon with the R.A.M.C. during the South African war, Ekins went to Egypt twenty-five years ago. Entering the Egyptian Government's Public Health Department, he served for several years in the provinces, and in 1906 was appointed director of the Alexandria State Hospital. There he remained for eighteen years, during which period he set himself to organize the hospital and to make and keep it efficient. From this Government post he retired in 1924, having done excellent service and gained the esteem and affection of all his colleagues, and established himself in practice in Alexandria. On January 1st, 1928, he was appointed physician, and on July 1st, 1928, medical director, to the Anglo-Swiss Hospital. Ekins was not only capable, but he was very human, optimistic, and kindly; he will be greatly missed by patients and by hosts of friends. He married eighteen years ago, and is survived by his widow.

We have to announce the death, at the age of 47, of Mr. DOUGLAS W. HUME, which occurred suddenly at his home in Bangor on February 12th. Mr. Hume received his medical education at St. Bartholomew's Hospital, obtaining the diplomas M.R.C.S., L.R.C.P. in 1906, and graduating M.B., B.S.Lond. in 1907. In 1914 he became a Fellow of the Royal College of Surgeons of England. In the course of a distinguished career at St. Bartholomew's Hospital he was awarded the Matthews Duncan exhibition in 1906, and the Bentley prize in 1909. During the period 1909–10 he was president of the Abernethian Society. For a short time after qualification he was house-physician to the East Sussex Hospital at Hastings, but returning to St. Bartholomew's Hospital he held a series of appointments from 1907 to 1915, including those of senior resident anaesthetist, house-surgeon, and ophthalmic house-surgeon. In 1915 he obtained the commission of major in the R.A.M.C., and until 1919 was surgeon specialist to the Norfolk War Hospital with charge of 1,040 beds. From 1919 to 1922 he was superintendent of two Ministry of Pensions hospitals at Exeter, remaining there till January, 1923, when he engaged in practice at Bangor, being shortly afterwards appointed honorary surgeon to the Carnarvonshire and Anglesey Infirmary. Mr. Hume was the author of a number of papers, including "A case of natural appendicostomy" (*St. Bartholomew's Hospital Journal*, 1910), "Ligature of subclavian artery for aneurysm" (*British Medical Journal*, 1910), "Ilio-tibial band grafts for cure of inguinal hernia (*British Medical*

Journal, 1921), "Slipping peroneal tendon treated by Kelly's operation" (*British Medical Journal*, 1922). Dr. J. Wilson Reid (Beaumaris, North Wales) writes: The death of D. W. Hume is a great loss to surgery in North Wales. The accuracy of his diagnosis and the excellence of his technique were only matched by the pains he took over every case, no matter how trivial. He was of a very retiring disposition, and never valued his own opinion highly enough, so that the world of medicine and surgery will lose by the fact that he did not publish more. He will be affectionately remembered by all who came in touch with him. The gap which his death leaves in our midst will be very difficult to fill.

The death took place in London, on February 28th, of Dr. ALISTAIR JAMES MACGREGOR, who formerly practised in Dunfermline and acted as medical officer of health for the burgh. Dr. Macgregor was a son of the late Dr. Duncan Macgregor of Pathhead and Tranent. He graduated M.B., C.M. at Edinburgh in 1888, proceeding to M.D. with honours in 1892. Shortly afterwards he commenced practice in Dunfermline, where he was a highly respected practitioner for between thirty and forty years. After taking the D.P.H. of Edinburgh in 1905, Dr. Macgregor became medical officer of health for Dunfermline, a post which he held till his retirement three years ago, when the post was filled by a whole-time medical officer. In this appointment he acted as medical superintendent of the West Fife Hospital for Infectious Diseases, and as tuberculosis medical officer to the Dunfermline Insurance Commission. He was also parochial medical officer for Dunfermline burgh and police surgeon. Dr. Macgregor took a great interest in many of the social activities of Dunfermline, and in particular was a prominent member of Dunfermline cricket club, being a cricketer well known throughout Scotland. He is survived by a widow and daughter.

Dr. JAMES STIRLING ROBERTSON, who died on February 13th, at his residence in Clydebank, after a brief illness, was the oldest member of the profession in the district. He received his medical education at Edinburgh, where he graduated M.B., C.M. in 1883. A colleague writes: So long ago as 1886 Dr. James Robertson was elected a member of the London Fabian Society, where, under the influence of its distinguished membership, and of his own natural bent, he became greatly interested in social problems, which presented themselves in plenty in the area where he practised. He was a J.P. for Forfarshire, a member at one time of the education authority, an active member of the British Medical Association, and chairman of the Local Panel Committee. He was a well-informed contributor to the press on social topics, and a highly esteemed member of the medical profession. His breadth of outlook, his keenness of mind, and his kindly counsel will long be remembered with gratitude.

Dr. PRICE MORRIS, who died on February 27th, at the age of 78, was for many years a well-known and popular figure in the district of Colwyn Bay and Colwyn. He was born in Llanfair Talhaiarn, where, at the early age of 16, he used to go about with Dr. Davies, the old custom of apprenticeship for a doctor being still prevalent. After his apprenticeship he went to Anderson College, Glasgow, where he obtained in 1874 the diplomas L.R.C.P.Ed. and F.R.F.P.S.Glas. After practising for a time at Hebden Bridge, near Halifax, and later in Cwmaman, Aberdare, he returned to Llanfair Talhaiarn, where he built up a most extensive practice over a sparsely populated area, removing later to Colwyn. From then until 1923, when failing health necessitated his retirement, he was engaged in active practice. He was very fond of fresh-water fishing and horses; he was chosen on several occasions to act as a judge of horses in the Colwyn Agricultural Show. In his early years he found time to ride to hounds with the Flint and Denbigh pack. In 1897 the Colwyn Bay Cottage Hospital was built; Dr. Morris, who was one of the prominent movers in its inception, held the appointment of senior surgeon to it until 1911, when he became consulting surgeon. For thirty years he was parish medical officer and vaccination officer to a district which included Colwyn Bay, Rhos, Glanconway, Dafarn Newydd, and Llysfaen. In the middle period of his life he was very fond of walking, and few of its inhabitants knew so intimately the geography of North Wales, especially West Denbighshire and the mountains and valleys of Merionethshire and Carnarvonshire. A colleague (A. N. L.) writes: Dr. Price Morris's merits as a doctor were outstanding, and he rose with success in every sense of the term for very many years. He was an exceedingly shrewd diagnostician and always knew his own mind, and was able to penetrate to the essential feature of a case while others were groping among the non-essentials. His very determination inspired his patients with the will to get better, and his visits have often been described to the writer as resembling a breath of sea breeze in the sick bedroom. He had the faculty of expressing himself in such a manner that he was always carefully listened to and his advice followed; though in no way eloquent, his arguments were cogent and clear, and at times he could be extremely dogmatic. For instance, in emphasizing the importance of fresh air in a case of consumption, he had been known to put his stick through the window of the cottage bedroom. His life was spent in the service of humanity, and in his business relations as well as in his professional work, he was always kindly and considerate to others.

Dr. FREDERICK CLAUDE EVILL, who died on March 3rd, at the age of 67, was the senior medical practitioner in Barnet, where he had practised since 1897. He received his medical education at St. Bartholomew's Hospital, and obtained the diplomas M.R.C.S., L.R.C.P. in 1886. After holding house appointments at St. Bartholomew's, the Central London Ophthalmic Hospital, and the Brompton Hospital for Consumption he went to Australia, and conducted a practice at Broken Hill, New South Wales, where he was senior surgeon to the local hospital. On returning to England he settled in Barnet, and was appointed surgeon to the Barnet Victoria Cottage Hospital. Apart from his medical practice he found time for active work in connexion with the Chipping Barnet Parochial Church Council and the National Society for the Prevention of Cruelty to Children. He had been a member of the Hertfordshire Medical and Panel Committees since their formation in 1912, and at one time was chairman. He was a strong supporter of the British Medical Association, and served on the Metropolitan Counties Branch Council from 1913 to 1926; he was vice-chairman of the West Herts Division in 1914, 1917–18, and in 1927, and chairman in 1915, 1919–21, and 1927–28. Ill health compelled his retirement from practice, but it was hoped that he would recover his strength; his regretted death was, therefore, unexpected. A colleague writes: We shall all miss Dr. Evill very much. He was of a particularly gentle disposition, and made an extraordinarily good chairman of our medical committee, his good nature acting like oil on the troubled waters of controversy.

THE LATE DR. J. F. BULLAR.

DR. A. NIVEN ROBERTSON writes: As one of the many house surgeons at the Free Eye Hospital of Southampton who had the good fortune to be trained in eye work under Dr. Bullar, I would like to add a few words to your obituary notice (February 2nd, p. 230) in appreciation of his great work in Southampton. He was the founder and maker of the Free Eye Hospital. When he started specializing in ophthalmic work in Southampton there was no eye hospital. He started a small eye clinic in one of the obscure streets of the town along with his faithful assistant, Miss Monk, the present matron of the Free Eye Hospital. It began in a very small way, but soon his great skill and ability it was not long before he obtained a name as a skilful ophthalmic surgeon, and the patients became so numerous that his activities were transferred to a building which is now the Free Eye Hospital of Southampton. This consisted of a large villa in its own grounds, and with the able administration of its founder, with the help of others whom he interested in his projects, this villa was gradually converted into a first-class hospital, with in-patients. The first floor contained the female cases and the ground floor the

cases. A room on each floor was added as an operating theatre. Previously the bathroom was the only theatre. A spacious waiting room was built, a dispensary was added, and all modern appliances were obtained, such as a large electro-magnet for the removal of foreign bodies. The docks always supplied a large number of such casualties. What astonished me most on my arrival there was that the chief did all his refractions in a room practically undarkened. I felt that it was an impossible task to do refractions in the light, but soon found that it was easy. He was a very skilful operator, and a past-master in the specialty which he had taken up. With all his patients he had a kindly way, and possessed a great gift of pawky humour. He treated all, rich or poor, alike. Sometimes to the wealthier classes, whom he treated at his own consulting rooms in Carlton Crescent, he seemed a little brusque, but he had a kind heart beneath his occasional off-hand manner, and I shall always remember the merry twinkle of his kindly eyes. He had no "side" about him; he was honest, and he was beloved by all who really knew him.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Local Government Bill.

Committee Stage in the House of Lords.

As briefly reported in this column last week, the House of Lords, in committee on the Local Government Bill on March 5th, discussed amendments to safeguard voluntary hospitals. Lord ONSLOW, who was in charge of the bill for the Government, moved an amendment of Clause 2. This amendment deleted the words "elsewhere than in the County of London" from a provision regarding the functions of Poor Law authorities in respect of infant life protection. Before amendment this section ran:

"functions under Part I of the Children Act, 1908, shall, elsewhere than in the County of London, be discharged by the councils of counties and county boroughs as functions under the Maternity and Child Welfare Act, 1918."

The House agreed to the amendment.

Clause 4 relates to administrative schemes, and provides that within six months after the passing of the Act the council of every county and county borough should prepare, and submit to the Minister of Health, a scheme of the administrative arrangements for discharging the functions transferred to the council under the Act.

Lord Reading's Amendment.

Lord READING moved to add the proviso:

"In so far as such scheme relates to hospitals the council shall take reasonable steps to seek and to continue to secure full co-operation with every voluntary hospital within, or serving the area of, the council."

He said he proposed this in the interest of voluntary hospitals to ensure that there should be full consultation with them before any action was taken which might impair their usefulness. These hospitals were in danger of being injured if the bill remained as at present. His purpose was to ensure co-operation with the voluntary hospitals and co-ordination so that there might be no overlapping of the work of rate-supported hospitals and voluntary hospitals, and so that the voluntary hospitals might be consulted in order that the best use might be made of existing institutions. This was intended by the framers of the bill. The words he proposed to insert were taken from the Local Government (Scotland) Bill, and appeared there almost identically in Clause 27. He knew the Minister of Health was in full sympathy with the idea. They should make quite clear what was the intention of the bill. He noted that an amendment on the subject had been put down by the Government that day which proposed to ensure that county councils should make such arrangements as they thought desirable for securing that the functions transferred to them should be exercised in consultation with some body in their area representing the voluntary hospitals. Lord Reading said he thought this provision would allay the apprehensions of those who were concerned with the voluntary hospitals. He asked whether, when the bill became law, the Minister of Health would draw the attention of councils to this proviso, because the clause as it stood was not mandatory. Supposing that under the functions conferred by the bill a council wished to start a new rate-aided hospital, he hoped the Ministry would emphasize that the council should first ascertain from the voluntary hospital that it was unable to do the work better. If the voluntary hospital was doing the work, and could perhaps do it better with the aid of the council, then it would be wrong to start a rate-aided hospital whose functions would overlap those of the voluntary hospital.

Lord Dawson's Amendment.

Lord DAWSON OF PENN had given notice to move to add to the clause:

"A council in preparing a scheme under this section shall have regard to the desirability of consulting (*a*) any body existing in the area which is so constituted as to be representative of the voluntary hospitals in the area, and (*b*) any body existing in the area which is so constituted as to be representative of the duly qualified medical practitioners in the area, including those on the medical and surgical staffs of any voluntary hospitals in the area."

He said he understood that for the convenience of the House all the amendments connected with hospitals were to be discussed together. He did not think that voluntary hospitals required any defence. Without them medical progress and the progress of nursing would not exist. He did not contemplate that in future there would be voluntary hospitals alone. Inevitably municipal hospitals must arise. They would arise slowly, and in their beginnings they should have the advantage of consultation with the great voluntary hospitals which now existed, and be brought into touch with their traditions. Those who knew about voluntary hospitals should co-operate with those who had little experience of curative medicine, and little or nothing to do with it. The medical officer of health was now the main person responsible to the councils on questions of health. As long as the councils dealt with preventive medicine that worked well enough, but when the councils were about to enter on the founding of hospitals, which would steadily grow, it was reasonable to bring to the aid of the medical officer of health those members of the medical profession who had spent their lives in the cure of disease. The whole-time medical officers of England and Wales numbered 1,740, whereas the medical men who were in active practice in England and Wales numbered 30,000. Could the great work of hospital management on which the councils were going to enter be undertaken without an organic nexus with those whose lives were spent in curative medicine? His amendment not only asked that councils in preparing schemes should consult representatives of voluntary hospitals, but that they should also consult the doctors of the district, who were competent to deal with the cure of disease. It was as easy to find a coherent body of medical men in any district as to find a coherent body representing the management of voluntary hospitals. Experience of the Poor Law was little or no help in the administration of a curative hospital. The status of the medical officers was different. Experience of the Poor Law might be a disadvantage in founding a hospital which was to approximate to the quality and work of the voluntary hospitals. In dealing with the health of the people it would be more and more necessary to have institutional treatment. Improvement in the quality of panel practice would depend largely on institutional provision. He did not deceive himself by thinking that voluntary hospitals alone were any longer going to be adequate to the needs of the country, and for that reason he was most anxious that some machinery of co-operation should be provided which did not depend on the will of the local authority nor upon which Minister of Health was in office. Should there come into office some Minister in favour of an entirely nationalized or municipalized medical service for the country, an opinion such as Lord Dawson expressed, if recorded in the bill, would make it difficult for him to transpose the medical policy of the country. Lord Dawson added that he was not wedded to the words of his amendment.

Lord JOICEY said no question in the bill aroused more interest in the country than this of the hospitals. Owing to taxation voluntary hospitals had difficulty in getting enough money to carry on their work, and as time went on it would be necessary for some contribution to be given if these hospitals were to continue in their present form. Anyone who had to do with voluntary hospitals realized that the services they gave through the medical profession and the nurses could not be so satisfactorily rendered by any hospital under the control of a local authority or of the Government. On Tyneside and the Wear the workmen had a system of contributing to the voluntary hospitals, and their representatives were put on the committees, providing a valuable body of men who took an interest in the hospitals. It would be disastrous if the great services of the voluntary hospitals were not assisted generously.

Lord ATKIN suggested that the amendment which Lord Onslow had put down on the subject was too restricted. It only proposed consultation with any body within the county which was considered to represent the voluntary hospitals. If no such body existed then no obligation would be placed upon the county council. It was essential that the new scheme should be started with the good will and co-operation of the medical profession. It was impossible to start a hospital system to which the poor could come freely and the moderately poor on making payment if necessary unless the medical profession and the general practitioners had some voice through their proper representatives in the organization. He supposed the new municipal hospitals, if founded, would wish to draw on the good will and services of specialists and consultants. Surely it would be right if such a scheme were devised after consultation with the medical profession as a whole. The British Medical Association represented,

for practical purposes, the whole of the medical profession, and had branches in every county, so there should be no difficulty in consulting the medical authorities.

Lord KNUTSFORD said those with experience of voluntary hospitals were extremely anxious to co-operate with the bill. They desired that any new hospital should not overlap and do the same work as the voluntary hospitals. They did not wish money to be wasted in carrying out work which might be done by a hospital set up by the county council across the road.

Lord JESSEL asked what would be the proper authority to consult in London. Would it be King Edward's Hospital Fund? He hoped the British Medical Association would have some say in the matter.

Lord READING said he supported Lord Dawson's proposal that the representatives of the medical practitioners should be consulted.

Reply for the Government.

Lord ONSLOW, for the Government, said there had been a valuable discussion of the bill as it affected the voluntary hospitals of the country. The Government desired to encourage the co-operation between local authorities and hospitals, from which so much might be expected in the future. The Government also wished to make the best use of existing institutions. They all knew what was meant by a voluntary hospital, but there was no precise definition of one. The first thing the Voluntary Hospitals Commission had had to do was to devise a definition, which worked fairly well for the purpose of distributing a Government grant, but could not be used at present because it did not include such institutions as mental hospitals. The amendment which later he would move for the Government proposed that county and county borough councils should themselves be judges of the bodies which might represent the voluntary hospitals of their districts. The Government proposed that the authorities should make arrangements for meeting these bodies, and the Minister of Health would be glad, in a circular or otherwise, to point out the disability of the fullest co-operation with the voluntary hospitals. Under the clause which he hoped to introduce local authorities could consult the local hospital committees where these functioned or were resuscitated for the purpose. These committees had developed in some places, and would become hospital councils in some county boroughs. Alternatively the local authorities could use the committees of the British Hospitals Association, which, he believed, were soon to be reorganized and put on a county basis. Voluntary hospitals committees, where they functioned, included representatives of the local authorities, of the medical profession, both general practitioners and consultants, and of voluntary hospitals, both large and cottage hospitals. Any hospital had only to join the British Hospitals Association and its views would be available to the local authorities through that channel. Lord Onslow understood that Lord Dawson accepted the Government amendment, as it covered the point put in the first part of his own amendment, but Lord Dawson desired to ensure consultation with some body representing the practitioners on the medical and surgical staffs of the voluntary hospitals in the area. Lord Onslow could not propose anything at the moment to meet this desire. He hoped on the report stage to add to the clause words providing that some of those consulted should be representatives of the medical profession in the district. He did not know whether King Edward's Hospital Fund would be the most suitable body for London. It was desirable to leave the local authority to choose the body which would best represent the voluntary hospitals in the district.

Lord HANWORTH said the clause Lord Onslow proposed to move was so loose that it carried out nothing. He suggested another form of words.

Lord READING then withdrew his amendment.

Lord DAWSON said he would not move his amendment now. He did so in the hope they would get more out of the Government than good intentions. The amendment proposed by Lord Onslow gave very little.

The House then agreed to Clause 4.

Clause 5, dealing with alternative powers of giving assistance, empowers councils to declare that assistance which can legally be given, either as poor relief or under seven special statutes, shall be given under these statutes, such as the Public Health Act, Mental Deficiency Act, and Maternity and Child Welfare Act.

Lord RUSSELL moved to add to the list of Acts "or any other enactment mentioned in the scheme."

The LORD CHANCELLOR, in resisting this amendment, said the Lunacy Act had been deliberately omitted from the list of enactments. Under the Lunacy Act a public lunacy authority could only deal with certified lunatics, but under an earlier section of the Lunacy Act a number of persons infirm in mind but not certified were in Poor Law institutions. If brought under the Lunacy Acts these persons must be certified, which would probably be undesirable, or the powers of lunacy authorities might be extended to deal with persons without certification, a controversial alternative. The Government thought that the question of taking lunacy out of the Poor Law altogether, as he thought the Royal Commission on the Lunacy Law recommended, should be dealt with when Parliament dealt with the Lunacy Acts. It was hoped to introduce comprehensive legislation based on the Commission's report.

Lord Russell's amendment was negatived.

Consultation with Hospital Representatives.

The House of Lords was again in committee on the Local Government Bill on March 6th, when Lord ONSLOW moved to insert, after Clause 12, the following new clause relating to consultation by councils of counties and county boroughs with bodies representing voluntary hospitals:

". . . The council of every county and county borough shall make such arrangements as they think desirable for securing that the functions transferred to them under this part of this Act in respect to the provision of hospital accommodation will be discharged after consultation with such body, if any, within the county or county borough as they consider to represent the voluntary hospitals in the area."

He said he moved this subject to the undertaking he had given Lord Dawson that on the report stage he would add words providing not only for consultation with the representatives of voluntary hospitals in the county or county borough, but also with the medical and surgical staffs of the voluntary hospitals. He had not had time to reconsider the wording of the clause.

Lord COZENS-HARDY remarked that hospitals, particularly those with medical schools, had spheres of influence which sometimes marched with the boundaries of a county or county borough. He asked for reconsideration of the words "within the county or county borough," and also of "voluntary hospitals in the area."

Lord DAWSON had given notice that, as an amendment to Lord Onslow's suggested new clause, he would propose to add words enjoining consultation by the local authority also "with any body existing in the area which is so constituted as to be representative of the duly qualified medical practitioners and of the medical and surgical staffs of the voluntary hospitals in the area."

Lord Dawson suggested that it would be unwise for the House to commit itself to the wording of Lord Onslow's clause, which did not meet the wishes of the friends of voluntary hospitals. Lord Onslow's offer to arrange for the representation of medical and surgical staffs of hospitals was not all that was desired. They wanted a body representative also of the duly qualified medical practitioners.

Lord Dawson did not move his amendment, and Lord Onslow's new clause was provisionally accepted.

Recovery of Maintenance Expenses.

Clause 15 places on the councils of counties and county boroughs and all other local authorities the duty of recovering from any person who has been maintained by them in an institution, other than an institution for treatment of infectious disease, all the expenses of maintenance or such part as the authority deem that person able to pay. Lord PARMOOR moved to leave out the operative part of the clause. He said it imposed on the county council an obligation to recover from any person who had been maintained in any hospital the incidental expenses incurred. This would prevent people from taking advantage of hospital treatment. Voluntary hospitals, by a well-known legal principle, had no power to recover charges in respect of patients. When a man was brought in who could afford an adequate payment they could not ask him to pay. At St. Bartholomew's Hospital, which treated over 100,000 patients in a year, there was no question of payment being enforced. The whole of medical and surgical science was at the disposal of a man, however poor. Why, when a county council provided treatment, were venereal disease and tuberculosis the only two infectious diseases for the treatment of which a charge would not be made?

The LORD CHANCELLOR said that when to-day the guardians provided relief for a person in an infirmary or in a workhouse the recipient and those legally liable to maintain that person were liable for the cost of the relief, and the guardians were under a statutory obligation to recover. If the clause were carried county councils would be able to recover expenses of treatment in hospitals maintained under the Poor Law powers, but not in those established under Public Health Acts. That was an indefensible anomaly. Infectious disease, which he understood to include scarlet fever and small-pox as well as venereal disease and tuberculosis, was treated differently, because a man was sent to hospital to protect his fellows from the risk of contagion.

Lord PARMOOR withdrew his amendment, and Lord Arnold moved another to make the recovery of the expenses of treatment optional instead of compulsory.

Lord READING regretted that the Government insisted on the provisions of the clause, but by 85 votes to 29 the House rejected the word "shall."

On a subsequent amendment which he proposed to the same clause Lord ARNOLD asked whether surgical tuberculosis was dealt as an infectious disease. Lord ONSLOW said he could not answer definitely.

Lord DAWSON said Lord Arnold's amendment was an illustration of the importance of having doctors who spent their life [illegible]

curable disease associated with the medical officer of health from the moment that councils undertook these questions. It would be impossible to draw up a list of what the medical profession regarded as infectious diseases, because knowledge was ever growing. The present opinion would be that a large number of cases of tuberculosis were not dangerous to the health of others. In many cases of surgical tuberculosis the danger of transmission of the disease was very small. The same might be said of cancer. The prevailing opinion was that cancer was not an infectious disease.

Lord BLEDISLOE agreed that opinion on the infectivity of disease varied with medical knowledge. A Royal Commission which sat some twenty years ago to consider the relationship between human and bovine tuberculosis had stated that tuberculosis was of a markedly hereditary character. That opinion had been scrapped by all enlightened medical men for at least fifteen years.

Lord ARNOLD withdrew his amendment, and a discussion followed on the propriety of recovering hospital costs from the relatives of patients.

Lord COZENS-HARDY moved to add a proviso that a local authority should not seek to recover cost of treatment from a patient or from his relatives when an association or fund for the support of hospitals had bargained with the council to pay an agreed charge in respect of that patient, being a person entitled to benefits from that association or fund. He said this was intended to help the associations which, by weekly contributions from employers and their workmen, had done much to relieve the financial anxieties of many voluntary hospitals.

Lord ONSLOW said the point was interesting and important, and had not been raised in the Commons. He asked time to consider it, whereupon Lord Cozens-Hardy withdrew his amendment.

Clause 15, and subsequent clauses, were added to the bill.

The Whole-time Medical Officer of Health.

The debate was resumed on March 7th, when Lord HALSBURY moved an amendment to Clause 53, which makes provisions regarding medical officers of health. The first section of this clause enacted that every county council, after consultation with district councils wholly or partly within the county, should formulate arrangements for securing by a combination of districts or otherwise that every medical officer of health subsequently appointed for a district should be restricted by the terms of his employment from engaging in private practice as a medical practitioner. Lord Halsbury moved to leave out all the words after "securing," and to insert "the future appointments by district councils of medical officers of health, whether by combination of districts or otherwise, which shall most conduce to the efficient carrying out of public health services within the county as a whole, as well as within the district to which they are respectively appointed." Lord Halsbury said it was true that at the end of Clause 53 a proviso enabled the Minister in exceptional circumstances to waive the condition that in future when any medical officer was appointed he should be appointed as a whole-time officer and not allowed private practice. That, however, was to be the ordinary and primary condition. The second report of the Royal Commission on Local Government was in accordance with the report as drafted, but this finding was based on evidence given by the Minister himself and by county councils and other administrative bodies which were thinking primarily of what would be most convenient for them. Undoubtedly whole-time servants would be more suitable for their purpose, and more easy to deal with; but the question really was whether the medical officer of health would not be more efficient in his district if he were to keep up the curative part of his work as a doctor and not be confined to an administrative position where he did not exercise his profession.

Lord ONSLOW said Lord Halsbury cut at the root of the recommendations with regard to medical officers made by the Royal Commission and embodied in the bill. The report of that Commission showed that the Rural District Councils Association considered it desirable that the medical officer of health should be a whole-time officer whenever practicable, although it was in the rural districts that the part-time officer was usually found. Lord Onslow cited a letter from the Medical Secretary of the British Medical Association to the *Times*, in which he said that the policy of that body as adopted in 1911 was that "in the general interests of public health and the medical profession it is desirable . . . that medical officers of health should, as a rule (and without prejudice to those at present holding part-time appointments), be required to devote their whole time to official duties." Lord Onslow said there had been a tremendous development of these duties in recent years, and the demand for specialized knowledge had made it necessary that the medical officer of health should have a diploma in public health. Further, the private practitioner had to attend to his private as well as his public duties, and it was undesirable that a man should be placed in a position where these duties might conflict. It was not necessary that the medical officer should serve one district alone. He might serve two or three districts or an urban and a rural district, but it was desirable that he should be a whole-time public servant. Another point was that there might be situations in which a private practitioner with great demands upon his time would have to choose between the interests of his private patients and his public duties. There was a provision in the bill whereby, when a system of part-time officers was working well, a loophole was given for their employment, but as a general rule the right policy to follow throughout the country was to have whole-time medical officers of health in accordance with the terms of the bill.

Lord HALSBURY thereupon withdrew his amendment, and Clause 53 was agreed to; as was Clause 54, which deals with the qualifications of certain medical officers and health visitors.

Maternity and Child Welfare.

Clause 55 is concerned with maternity and child welfare services. It provides that in any district where services under the Maternity and Child Welfare Act are provided by a council which is not the local educational authority, the Minister may, on the representation of that educational authority, and if he is satisfied that the change would conduce to more efficient administration, transfer to the local health authority the maternity and child welfare duties which are being performed by the other council.

Lord ARNOLD moved to insert an amendment providing that, when taking such action, the Minister should have regard to local conditions and requirements. He said the amendment would withdraw maternity and child welfare services from the councils of certain urban districts which had grown rapidly in the last twenty years, but were not educational authorities. He instanced the cases of Coulsdon, Purley, Sutton, and Barnes. He also wished to ensure that the Minister should not be able, on the application of the county council, to transfer maternity and child welfare services to the county council unless satisfied that the transfer would conduce to more efficient administration, having regard to local conditions and requirements. Lord Arnold said that under this bill the county councils would be overburdened without the necessity of administering maternity and child welfare schemes, which had for years been administered by others. Why should Parliament upset existing arrangements if they worked well?

Lord ONSLOW said the Maternity and Child Welfare Act of 1918 had provided that a district could become a maternity and child welfare authority, but the bill encouraged and provided machinery for the transfer of these duties to a body which was a school medical authority. The clause, however, provided a great deal of latitude so as not to interfere with the child welfare committee which was doing good work. The reason for the policy of combining child welfare functions under an authority which was also a school medical authority was to place the supervision of the child and the mother also under the care of one and the same local authority from pre-natal days until the child ceased to be of school age. Provision was made to bring the midwives under the same supervision as the maternity and child welfare authorities. It was desirable that the school medical authority should be under the same body. They might trust the Ministry of Health to see that, in order to obtain uniformity, they did not take away what was being well done already. Uniformity would be obtained gradually.

Lord ARNOLD said he thought Lord Onslow's reassurance would do something to remove misgivings. The amendment was withdrawn, and Clause 55 was added to the bill, as was also Clause 56 dealing with notification of births.

Clause 57 enacts that if the council of any district has established a child welfare and maternity committee and employs a medical officer of health, who, by the terms of his appointment, is restricted from engaging in private practice, that council may apply to the Minister to be made the local supervising authority under the Midwives Act, and the Minister may so direct after consultation with the county council.

Lord HALSBURY moved to limit this to councils which were also local educational authorities. He said the amendment would provide larger areas for the control of midwives than did the bill. Midwives objected that if they were under the control of small areas their work would take them outside those areas, and they would find themselves under a dual control with conflicting rules and regulations made by the district council and the county council. If the district were that of the local educational authority it would be a district of some size. The larger the area the less likelihood of such local difficulty as that of a doctor preferring one particular midwife because he had been working with her and employing her to the exclusion of others. Furthermore, it would be much easier to get an experienced inspector for the larger area. Under the Midwives Act, 1902, there was power for counties to delegate the inspection of midwives to a smaller area. Ten counties adopted that, but every one of them, after trial, gave it up.

Lord KNUTSFORD said he was authorized to say that the Central Midwives Board objected to the transfer of powers of inspection of midwives from the county council to a district council. Objection was also taken by Queen Victoria Jubilee Nurses, by the Incorporated Midwives' Institute, and by the College of Nursing. This was the first opportunity there had been of voicing the unanimous opinion of every one of the bodies concerned with

midwives. It would be impossible for the district council to employ a whole-time inspector of midwives' work.

Lord ONSLOW drew the attention of the House to the recommendations of the Royal Commission on which the clause was based. The Commission recommended that the county council should transfer these functions to a district council only when the Minister was convinced that the district council was in a position to discharge the whole of the functions of the local supervising authorities. A number of towns approaching the 50,000 limit had felt some displeasure because these duties had been taken away from them, and the clause was directed to meet the case of such towns. He did not think that the interest of the midwives was likely to be injured by its provisions.

In asking leave to withdraw his clause, Lord HALSBURY hoped that before the report stage Lord Onslow would consider whether the midwives themselves should be given some say in the matter. The House then agreed to Clause 57, and also after a technical amendment to Clause 58, which deals with the provision of hospital accommodation for infectious disease.

The committee stage was completed on March 8th. On that day Lord BUXTON moved an amendment to Clause 78, which provides for the discontinuance of grants set out in the schedule to the bill. He moved to insert "other than grants for maternity and child welfare." He said that under the existing system when a local authority wished to institute or extend a maternity home or child welfare institution the Ministry of Health gave a grant, pound for pound. If these services were brought, as the bill intended, under the block grant system no additional grant for the extension of maternity and child welfare work would be given. The Government grant for these services had risen from £12,000 a year in 1924 to just over £1,000,000 a year, and there were 2,634 centres. The present system had been a great stimulus to the centres, but that was a reason for giving them greater encouragement instead of damping them down. He did not think that the method suggested in the bill whereby a Minister could force a recalcitrant authority to institute or extend these centres was a good one.

Lord BUCKMASTER said the British ratio of maternal mortality was a disgrace. Compared with those in Holland the deaths were as 14 to 2. There was hardly a medical man who would not say that maternal mortality was almost entirely preventable, as in Holland.

Lord ONSLOW said Lord Buxton's amendment would alter the bill fundamentally, cutting at the root of its financial system. A percentage grant was a stimulus to the richer areas, but maternal mortality was in the poorer districts, which could not afford to raise the initial sovereigns to get this pound for pound grant from the Government. To enable those poorer areas to get the necessary money for their services the Government had brought forward the block grant. It was the duty of the Minister of Health to see this service was effectively carried out. Local authorities would be told they would not get the money unless they spent it properly.

Lord Buxton's amendment was negatived, and Clause 78 approved.

The House approved Clause 93 and subsequent clauses, including those dealing with transferred officers, compensation to existing officers, and the superannuation of transferred Poor Law officers. Amendments on these provisions were moved, but withdrawn, and the committee stage was completed.

Bills.

The Factory and Workshops (Cotton Cloth Factories) Bill formally passed through report stage in the House of Lords on March 5th. On March 7th it was read a third time and sent to the Commons.

The Mount Vernon Hospital Bill was read a second time in the House of Lords on March 7th, on the motion of Lord Donoughmore, chairman of committees.

Small-pox.—In an answer to Mr. T. Griffiths, on March 7th, Mr. CHAMBERLAIN said the number of deaths classified as due to small-pox for the purposes of the Registrar-General's statistics during the thirteen months ended January 31st last was 58. No statistics were available giving the total number of deaths from influenza during the current year. He was aware of the importance of early medical attention in cases of influenza, but he saw no reason to empower the guardians of rural parishes to make emergency orders for medical and other relief in cases of illness. Answering a further question, Mr. Chamberlain said he had seen the statement of the medical officer of health for Stepney that many cases of small-pox had been mi[illegible] special instructions had been issued by [illegible] advising medical officers to take special [illegible] of such occurrences, but the matter had been referred to in a circular issued by the department last year, and in the annual reports of the chief medical officer. Mr. Chamberlain, on March 7th, also told Mr. Groves that the figure of 37 deaths from small-pox in the first half-year of 1928, given in the chief medical officer's annual report for 1927, were, as explicitly stated in the report, provisional.

Vaccination and Encephalitis.—Mr. CHAMBERLAIN, replying to Mr. Groves, on March 11th, said that from October 1st, 1927, till December 31st, 1928, 65 cases in which symptoms suggestive of disease of the central nervous system within a month of vaccination had been brought to the notice of his department. Of these, 32 were fatal. All cases of this kind were reported to the Departmental Committee on Vaccination, but he was not yet able to say how many of these 65 cases were regarded by the committee as cases of encephalitis following vaccination.

Silicosis.—Sir W. JOYNSON-HICKS, on March 11th, told Mr. Kelly that local joint committees of employers' and workers' representatives had been set up under the Refractories Industries (Silicosis) Scheme for seven areas. A scheme now under consideration for the sandstone industry provided for the appointment of similar committees to deal with cases of silicosis in that industry. The areas and constitution of the committees under this new scheme would be settled in consultation with the employers' and workers' associations.

Mental Deficiency.—Dr. FREMANTLE asked Mr. Chamberlain, on March 7th, the date of publication of the second section of the report of the Departmental Committee on Mental Deficiency. Mr. CHAMBERLAIN said he could give no undertakings about any portions of the report save the section which Lord Eustace Percy had promised to publish. He had not yet had time to consider it properly. Dr. FREMANTLE remarked that the report was extraordinarily important.

Census of the Insane.—On January 1st, 1929, the insane patients in England and Wales were: in county and borough mental hospitals 115,690, in registered hospitals 2,034, in licensed houses 2,615, making a total of 120,339. A previous answer by Sir John Gilmour showed that, on the same date, the total number of lunatics in Scotland was 18,917.

Poor Law Relief.—Mr. CHAMBERLAIN states that in January, 1929, the number of lunatics in asylums under the Poor Law, persons in receipt of domiciliary medical relief, and casuals was approximately 127,000. On January 12th the number of persons in receipt of other forms of Poor Law relief in England and Wales was 1,141,997. The latest figure available for the number of persons in receipt of relief in Scotland, exclusive of vagrants, is 209,461, on September 15th, 1928.

Sanitation in the Hop Gardens.—Mr. CHAMBERLAIN announced, on March 7th, that the terms of a further general communication to Kentish local authorities with reference to sanitary conditions during the hop-picking season were being considered. In three instances last year representations from the Ministry of Health had led to the adoption of an improved code of by-laws.

Notes in Brief.

Mr. Chamberlain cannot undertake to introduce legislation empowering local authorities to close redundant slaughter-houses.

The question of payment of midwives for emergency work will be considered by the departmental committee appointed to inquire into the working of the Midwives Act.

In the year 1928 the number of convictions for drunkenness in the Metropolitan Police district were: males 18,364, compared with 21,177 in 1927; females 4,916, compared with 5,977 in 1927. In the City of London the equivalent figures were: males 280, compared with 298; females 81, compared with 84.

Mr. Chamberlain has no information showing the approximate number of inhabitants of condemned houses in England and Wales, nor the approximate number who live in areas designated as slums.

[The report on the Local Government (Scotland) Bill has been held over until next week.]

Medical News.

SIR HUMPHRY ROLLESTON will give a lecture on industrial disease and its prevention before the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1, on March 21st, at 3 p.m., with the Duke of Northumberland in the chair. At the sessional meeting of the Institute to be held in the Council House, Birmingham, on April 5th, Mr. H. H. Humphries will open a discussion on some drainage problems in Birmingham, and Dr. H. P. Newsholme will open a discussion on co-ordination and co-operation in preventive medicine.

AN industrial nursing conference, arranged by the Industrial Welfare Society, will be held at the Hotel Metropole, London, on April 19th. Lady Dawson of Penn will receive the nurses at an evening reception. On April 20th visits will be made to several factory clinics, so that the delegates will have an opportunity of seeing industrial nursing in practice.

UNDER the auspices of the National Council for Mental Hygiene, Sir C. Hubert Bond will deliver a lecture on the mental hospital of to-day, at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Wednesday, March 20th, at 5 p.m.

AT the meeting of the Royal Microscopical Society in the lecture hall at 20, Hanover Square, London, on March 20th, at 7.30 p.m., a discussion will be held on Dr. H. Moore's paper on "The mode of formation of the image in the microscope." The biological section will meet in the library on April 3rd.

THE annual business meeting of the Mental After Care Association will be held at Bridewell Royal Hospital, New Bridge Street, E.C., on Tuesday, March 19th. The president, Sir Charles Wakefield, will take the chair at 3 p.m.

THE last of the present series of lectures arranged by the Fellowship of Medicine will be given at the Medical Society, 11, Chandos Street, W.1, on March 18th, at 5 p.m., when Mr. H. W. Carson will speak on pitfalls on the right side of the abdomen. The final demonstration of the series will be given at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C.1, on March 20th at 4 p.m., by Dr. S. H. Daukes, on the various methods of drug administration. The lecture and demonstration are free to medical practitioners. There will be no further special courses until after Easter. Those taking place in April are as follows: a daily practitioners' course, 4 to 5.30 p.m., at the London Temperance Hospital, April 8th to 19th: a course in tropical medicine at the London School of Hygiene and Tropical Medicine, April 9th to May 2nd; electrotherapy at the Royal Free Hospital, on Wednesdays at 5.15 p.m.; medicine, surgery, and gynaecology at the Royal Waterloo Hospital, April 15th to May 4th; and a course in neurology at the West End Hospital for Nervous Diseases, from April 15th to May 11th, at 5 p.m. daily. Detailed syllabuses of these courses, with information about the general course of work at the various London hospitals, and copies of the *Post-Graduate Medical Journal*, may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A NEW series of specially conducted tours is being arranged this year under the auspices of King Edward's Hospital Fund for London. The first is a visit to the Regent and Gerrard telephone exchanges on Saturday, March 23rd, at 2.30 p.m., when the Assistant Controller of Telephone Exchanges will explain the working of the telephone system. Tickets (price 7s. 6d.) may be obtained from the Secretary, King Edward's Hospital Fund for London, 7, Walbrook, E.C.4.

THE funeral of Sir Hector Mackenzie took place at Highgate Cemetery on March 6th. A memorial service held in St. Thomas's Hospital Chapel was attended by a large gathering of members of the medical profession and representatives of bodies with whom he had long been associated.

THE programme has now been issued for the Congress of the Royal Institute of Public Health to be held in Zürich from May 15th to 20th. The subjects of sectional discussions are State medicine and municipal and social hygiene; industrial hygiene and industrial diseases; child welfare, school hygiene, and women and public health; pathology, bacteriology, and biochemistry; tuberculosis; climatology and sports hygiene; and veterinary medicine and meat hygiene. In connexion with the congress visits are being arranged to Rheinfelden, the Rhine Falls and Schaffhausen, and other places of interest. Extensions to Lucerne, Leysin, Innsbruck, Munich, and Czechoslovakia are also practicable. Further details about the congress may be obtained from Dr. T. L. Kelynack, 37, Russell Square, W.C.1.

THE Minister of Health has expressed his approval of a proposal to invite the International Union of Local Authorities to hold its next congress in 1932 in this country. A unanimous resolution in favour of such an invitation being given was passed by the Association of Municipal Corporations in November last. Resolutions in sympathy with this action have been since passed by the Corporation of the City of London, the London County Council, the Parliamentary Committee of the County Councils Association, and the Urban and Rural District Councils Association.

A TOUR is being arranged for the middle of July to include various climatic resorts and spas in North Spain; it is proposed to visit San Sebastian, Bilbao, Santander, Burgos, Santillana, and Altamira, among other places. The tour will last about ten days and be conducted in charabancs; it is limited to medical practitioners and their wives and daughters. Further information may be obtained from Dr. M. Mañero, Ronda del Conde Duque, Madrid.

A POST-GRADUATE course in children's diseases will be held in Paris from April 3rd to 13th, at the Hôpital des Enfants-Malades, 149, Rue de Sevres. The fee is 250 fr., and further information may be obtained from the secretary of the Faculty of Medicine of the University of Paris.

THE first annual conference week of the International Society of Experimental Phonetics will be held in Hamburg from July 24th to 31st. Addresses, demonstrations, and practical work will be arranged, and there will be an exhibition of apparatus. Further information may be obtained from Professor E. W. Scripture, 25, Howard Road, Coulsdon, Surrey.

THE thirteenth International Congress of Physiology will be held at Boston, U.S.A., under the presidency of Professor H. H. Howell, from August 19th to 23rd.

WE have received the first issue, published in January, of a new monthly journal, entitled *Revue Belge des Sciences Médicales*, which is the official organ of the Medical Section of the Scientific Society of Brussels. The editorial staff consists of Professor L. De Beco of Liège, Drs. J. F. Heymans of Ghent, A. Lemaire and J. Maisin of Louvain, and A. Bessemans and J. Rodhain of Brussels. The first issue consists of original articles, clinical records, a survey of recent work on haematology, abstracts from current Belgian literature, and reviews of books. The subscription is 80 francs for Belgium, 100 francs for France, and 175 francs for other countries.

THE Amalgamated Press Ltd. is issuing in about thirty fortnightly parts a popular presentation of modern biological principles, entitled *The Science of Life*, written in collaboration by Mr. H. G. Wells, Professor Julian Huxley, and Mr. G. P. Wells.

THE issue of the *Journal of the Egyptian Medical Association* for December, 1928, is a special historical number, printed in English, French, German, and Arabic, and containing articles on ancient and modern Egyptian medicine and the evolution of public health administration in Egypt. It is copiously illustrated with photographs and diagrams of surgical instruments found in the course of excavation or depicted on the walls of temples.

MR. BERNHARD BARON, who recently gave £10,000 for a new casualty department at the Royal Sussex County Hospital, Brighton, has notified the authorities of his intention to contribute £5,000 towards a new operating theatre.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscern Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62559 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

INSOMNIA IN CHILDHOOD.

"P. F. C." asks for suggestions for the treatment of a boy, aged 4, with normal development and previous good health, except for long-standing constipation and nocturnal enuresis. During the past five months he has woken up regularly at about 2 a.m., when he chatters and plays, refusing to go to sleep. An uncle suffers from epilepsy, but otherwise the stock is healthy.

ENURESIS.

DR. R. E. M. TAUNTON (London, W.7), replying to "K." (March 9th, p. 485), writes: I suggest trying Dr. H. C. Cameron's glucose prescription, which in many cases I have found to be effective. To 1 lb. of liquid glucose add two pints of water and one or two lemons. Boil down to one and three-quarter pints and bottle it. The dose is 2 oz. three times a day. This causes no gastric symptoms or glycosuria, and enuresis often ceases after the first day's administration of the glucose.

INCOME TAX.

Partial Use of Car for Private Purposes.

"W. M. K." states that his car is used for private purposes one month in each year. The inspector of taxes proposes to exclude from the total car expenses £10, as representing part of the year's cost of insurance, wear and tear, and licence. "W. M. K." contends that that is wrong, because those expenses are not increased by private use—that is, they would be the same if the car were left in the garage during the holiday month.

*** We think that there is little, if any, prospect of contesting successfully the inspector's view. The general practice where private benefit is derived from business or professional expenditure is to make some reasonable allocation between the two, and we fear it is too well settled to be disturbed in such circumstances as are explained. It is not entirely inequitable.

Cessation of General Practice Work.

"G. M. C." sold the practice as from January 1st, 1928, did no professional work for four months, and since then has been taking clinics and giving lectures. What should be done to avoid being charged income tax for 1928-29 on the basis of the earnings for 1927—the previous year.

*** The previous year's basis applies to the calculation of the amount of profits assessable for a particular source of income. As "G. M. C." is not assessable for 1928-29 in respect of the sort of profits earned in the previous year—that is, the earnings of general practice chargeable under Schedule D—that basis has no application. "G. M. C." should write to the inspector of taxes dealing with the assessment, stating the full facts and undertaking to supply an amended statement as soon as possible of the actual earnings for the year ending April 5th, 1929.

LETTERS, NOTES, ETC.

QUININE IN INFLUENZA.

DR. H. B. GLADSTONE (London, S.E.) writes: A note on the treatment of influenza in the *British Medical Journal* of March 9th (p. 486) prompts me to advocate the use of quinine, which Burney Yeo in his handbook of treatment regarded as as much a specific in influenza as in malaria. After dabbling in the coal tar products this view was urged on me by a late member of Guy's staff, and since then, for at least fifteen years, I have used quinine and found it a specific. In the 1918 epidemic 2 grains every four hours did not seem to benefit, so I doubled the dose. The type was a severe one, and the remedy had to be stronger. The result was striking; cases that were stuporose became quite bright in twenty-four hours after taking 2 grains every two hours. In a small institution, where infants were admitted, as an emergency measure, from homes where the mother was ill with influenzal pneumonia, several of which had the complaint, among a staff of eight nurses only one contracted the disease, and that in a fugitive way, because they were all given 2 grains of quinine four-hourly as a preventive. Influenza is a disease where the toxins depress the nervous system, and sedatives are dangerous. The complaint needs tonic treatment from the first—quinine for five days, with aspirin for the first two days for the pains (if severe), then strychnine and hypophosphites, or calcium lactophos. A sedative linctus is usually needed for night cough. Although quinine is a popular remedy, *skill is required in carrying on the treatment, so one is not* merely doing what any layman can do, and complications have to be met. Some patients cannot take quinine, and then sedatives and coal tar products are really beneficial. Here the nervous system is already overexcited, and nerve stimulants would do harm; but in 90 per cent. of cases this does not come in. Quinine acts as an antiseptic as well as a tonic. It is best given in solution—not in pill form—as then it disinfects the throat in swallowing. For this reason (local action) small doses given frequently are better than massive doses at longer intervals.

THE HOUSEHOLD MEDICINE GLASS.

DR. T. R. E. HILLIER (London, N.W.) writes: A very large number of people nowadays use a medicine glass in place of the "domestic" measures—namely, the teaspoon, dessertspoon, and tablespoon. Theoretically, this is a step in the right direction, but let us see what it means in practice. I should say that 99 per cent. of the medicine glasses in use by the layman (and by some doctors I) are in the shape of a diminutive tumbler. These are quite accurate when it is required to measure an ounce or half ounce, but I defy anyone to measure accurately a drachm with one—an ordinary teaspoon is preferable, though the size of these spoons varies a good deal. Now many medicines are prescribed in drachm doses, particularly in the case of children, where the need for accuracy is even greater. There is only one common-sense form of glass, and that is a conical one, with a broad substantial base, marked clearly in teaspoons and tablespoons. Conical measures can, of course, be obtained, but they are almost invariably marked in drachms and ounces—of little use to the ordinary lay person. Moreover, people usually take what is offered them, and this is always the "little tumbler." Bottles marked with the doses may be suggested as a remedy, but most people pour out too much and will not be bothered to replace the excess, or too little, thinking it will be "near enough." All this may appear very obvious, but nevertheless I have proved it to be a matter of considerable importance.

OATMEAL, VITAMIN D, AND CALCIFICATION.

DR. J. D. MACKAY writes: The report by Mrs. Mellanby and Dr. Lee Pattison, on December 15th, 1928 (p. 1079), makes a point which I have not yet seen emphasized in your correspondence columns, the importance to the industrial population of their statement that "cereals, and especially oatmeal, inhibited perfect calcification of the teeth when this vitamin [D] was deficient in the diet." A large amount of oatmeal is consumed by the youngsters of the industrial population under these conditions of deficiency; for working people will not, or cannot, buy sufficient milk—half a pint of milk, perhaps, or a small tin of condensed skimmed milk, to last a few days. There are other sources of vitamin D, but the course which seems to recommend itself would be to forbid oatmeal, and to use, as a substitute, wholemeal (wheat) or wheat-meal. These millings, alone or mixed, make excellent porridge and other things in which oatmeal is used, and would appear to be free from the defects of the latter. There is, however, another point on which this attribute of oatmeal—the prevention of calcification—has given rise to speculation: has it any value at the other end of the scale, in the later years of life? Will a diet of oatmeal, under suitable conditions, prevent calcification where it is *not* wanted? Perhaps these eminent investigators, to whom the thanks of the whole nation are due for their labours, might express an opinion. This latter hope seems the only consolation to the Scots for this sacrifice of their historic diet on the altar of progress; a vision of wild old men champing their oats is at least stimulating.

PAINFUL SHOULDER.

"T. F.," referring to Mr. P. B. Roth's letter on traumatic synovitis of the shoulder, published on December 22nd, 1928 (p. 1156), writes: I have suffered from pain in both shoulders following injuries, the first nearly two years ago, the second more recently. The symptoms have been precisely those described by Mr. Roth. The pain and occasional tenderness have been most marked over the insertion of the deltoid into the humerus, and under the outer third of the clavicle. It has seemed to me to be highly improbable that the symptoms have been due to synovitis, as has been suggested. On the first occasion, while jumping off my bicycle, I fell on one knee, and, to save some plants I was carrying, I must have forcibly contracted the muscles of the shoulder—so forcibly, I concluded from what followed, that some muscular injury must have been caused. The trouble lasted for about four months. The second injury was occasioned by a more serious fall, but there again it may have been caused by a sudden forcible attempt to preserve equilibrium. The immediate pain in the shoulder was severe, and necessitated lying by the side of the road for some time to avoid fainting. This fall occurred within two weeks of six months ago. I still cannot put my hand in my trousers pocket without pain, and I am wakened regularly every night by pain, chiefly near the insertion of the deltoid into the humerus. One symptom not mentioned previously has suggested to me that the innervation of muscles about the joint may have suffered in some way. There has been, and in a minor degree still may be, a sudden jerking of the arm at the commencement of a movement, such as forcibly thrusting a spoon into a coffee cup; this causes spilling of the coffee. The improvement in my condition is so slow that I anticipate another six months passing before all the symptoms disappear.

TYPICAL FLIES.

DR. F. H. HAINES (Ringwood) writes: I note your review of E. K. Pearce's *Typical Flies* on March 2nd (p. 405). The photographs seem to be extraordinarily good. They are designed to give an idea of the "facies" of the species represented and not of the smaller structural points, although they often do this. They compare most favourably with similar illustrations in certain recent classics on other orders of insects, and would give a beginner the "hang" of the families. Your reviewer's sample of the notes is, I think, hardly fair, nor his comment thereon. It is of first importance to know the colour of the insect the tyro wishes to identify. If thousands of insects are black, thousands are not! Has your reviewer tried to reproduce a whole insect in focus?

MEDIAEVAL TOWNS AND SPAS OF GERMANY.

MR. HENRY BAERLEIN writes: Attention was drawn in your columns by a news paragraph which appeared in your issue of February 16th (p. 330) to a projected tour at Whitsuntide to the mediaeval towns and spas of Germany. This tour I was organizing on the lines of previous expeditions to Czechoslovakia and Jugoslavia, and was aiming at again having between twenty and thirty participants. After the appearance of the notice in the *British Medical Journal* a number of doctors wrote to me for details, but have not yet decided to go; may I point out that if the number of acceptances by the end of March falls short of twenty the tour cannot take place, as the agency in whose hands the management lies cannot for any smaller number make the proper and economical arrangements, either at hotels or in trains. Prospective travellers should send a deposit of £15 to me at the Bath Club, 34, Dover Street, London, W.1, which will be immediately returned if the numbers still fall short of twenty by March 31st.

A DISCLAIMER.

MR. A. P. BACHA, F.R.C.S., writes from Bombay disclaiming all responsibility for a paragraph which appeared in the local vernacular press referring to his professional work and attainments. He protests strongly against the deliberate use of such publicity in the Indian press.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 56, 58, 59, 62, 63, and 64 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 60 and 61.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 67.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

254. "Agranulocytosis."

W. C. HUEPER (*Arch. Intern. Med.*, December, 1928, p. 893) recalls that Schultz, in 1922, described a type of necrotic angina accompanied by a marked absolute and especially granulocytic leucopenia, and regarded these symptoms as manifestations of a disease which he called "agranulocytosis." Since then about 125 cases have been recorded under this name or that of "agranulocytic angina" (Friedemann). Hueper now records observations on five cases seen between November, 1927, and April, 1928. The etiology is unknown. Most authorities regard it as an infectious disease representing a septicaemia with an atypical reaction of the haemopoietic system, due either to bacteria with a special affinity and toxicity to the granulocytic system or to an atrophy and aplasia of this organ caused by septic infection. According to these investigators the bacterial cause is either non-specific or specific (streptococci, *B. pyocyaneus*, or fuso-spirillosis). The disease starts after a period of prolonged ill health, or, more frequently, in previously healthy subjects, with high continued fever, malaise, dysphagia, and dyspnoea; slight jaundice is present in about 50 per cent. The patient rapidly gets worse, and death occurs after coma of two to seven days' duration; there may be rarely remissions of a few days to several weeks. The outcome is usually fatal. At the onset the tonsils are enlarged and reddened, and show yellowish-white plugs, which merge to form dirty grey or yellowish coats; on removal of these an ulcerated surface appears. Sloughing of the tonsils rapidly ensues, and a similar necrotic process may be found on the pillars, uvula, palate, tongue, pharynx, gums, anus, vulva, vagina, and cervix. Staphylococci, streptococci, and pneumococci are the organisms usually found in the throat. The blood shows a considerable leucopenia; the granulocytic cells decrease first and may disappear completely, but there is also a lymphocytic diminution, which closely follows that of the granulocytic cells. The red cells are normal or exhibit only slight changes. Blood cultures are positive in only 10 per cent., when they contain haemolytic and non-haemolytic streptococci, *Streptococcus viridans*, *B. pyocyaneus*, *B. acidi lactici*, and *B. coli*. The disease is far more frequent in women than in men and mainly affects the middle-aged; it is apparently non-contagious. The prognosis is bad, but not absolutely hopeless. Recovery has followed the use of anti-streptococcus serum and *x*-ray applications to the long bones.

265. Intradermal Vaccination.

DURING the past fifty years many methods of vaccination have been advocated as being improvements over existing ones, but all of these have not proved equally satisfactory. C. ARMSTRONG (*Journ. Amer. Med. Assoc.*, November 17th, 1929, p. 1530) believes that new methods should be proved by adequate tests to be equal or superior to established ones, and that the superiority should be demonstrated not alone in the percentage of "takes," but also in the character of the local and general reactions and in the relative freedom from complications. The methods should also be practically free from the possibility of error which might prove harmful to the patient. He discusses, somewhat critically, the advantages claimed by Toomey and Hauver of the intradermal injection of the virus, and concludes that it is wise to employ a well-tried satisfactory conservative method, such as the multiple pressure one. In this procedure the insertion is made through a drop of lymph by pressing the side of the needle point rather firmly against the taut skin and raising and lowering it from twenty to thirty times. The pricks should cover an area never more than one-eighth of an inch in greatest diameter. The fluid is wiped off immediately, and, as the trauma is scarcely visible, a shield or dressing, which may lead to unsatisfactory results, is useless. This method gives a typical vesicle of maximum firmness, since the procedure neither removes nor destroys the epidermis, and thus there is little chance of accidental infection.

266. Severe Scarlet Fever.

S. I. EDELMANN (*Jahrb. f. Kinderheilk.*, January, 1929, p. 322) states that during the period 1919 to 1924 804 cases of scarlet fever were admitted to the infectious department of the children's clinic of the Second State University at Moscow. Of these, 120, or 14.9 per cent., were classified as severe, 23 being toxic, 43 septic, and 54 a combination of the two. Of the 120 patients, 89 died, a mortality of 69 per cent., 10 deaths taking place within twenty-four hours of admission. The severity of the attack was due to two factors—namely, affection of the vascular nerve supply and local involvement of the heart and cervical glands. In toxic scarlet fever the symptoms are those of involvement of the sympathetic nervous system, while in septic cases necrosis of the throat, nasopharynx, and cervical glands, and septicaemia develop at an early stage. The prognosis in cases with cervical cellulitis and early septicaemia is very unfavourable, the percentage mortality being highest in such cases. The complications of severe scarlet fever in order of frequency are adenitis, otitis, pneumonia, and nephritis. Although cardio-vascular disturbance is frequent, myocarditis and endocarditis are very rare, the latter especially so. Moser's serum was found to be the only measure which had any effect on the course of toxic scarlet fever.

267. Prophylactic Inoculation against Pulmonary Infections in Children.

IN the course of about fifteen months J. MINET and WAREMBOURG (*Journ. de Med. de Paris*, December 6th, 1928, p. 981) inoculated 50 cases of measles and 29 of whooping-cough in children, aged from 3 months to 15 years, who were admitted to the infectious diseases department of the Hôpital Saint Sauveur at Lille. The vaccine employed contained, in 1 c.cm., 100 million pneumococci, 50 million streptococci, 350 million staphylococci, 100 million enterococci, and 600 million *B. pyocyanei*. Although the wards were very crowded the results were excellent. Apart from a mild case of broncho-pneumonia no patient developed any respiratory complications, although several had more or less severe bronchitis on admission, or even patches of congestion. The dosage of the vaccine was as follows: 1/2 c.cm. up to the age of 2 years, 1 c.cm. from 2 to 5 years, and 1½ c.cm. after 5 years, given on admission, and repeated two days later.

268. Subacute Bacterial Endocarditis in Childhood.

G. M. LAWSON and R. S. PALMER (*New England Journ. Med.*, December 13th, 1928, p. 1205) review the literature, including Schlesinger's article (see *Epitome*, June 23rd, 1928, para. 610) dealing with the youngest case on record, the child being only 5 years old; they state that in their experience at the Massachusetts General Hospital the earliest age at which subacute bacterial endocarditis has occurred was 6 years, and the next earliest 8 years. The present authors record three fatal cases, in children aged 6, 8, and 10 years, and describe a very unusual case of *Streptococcus viridans* infection in a male infant aged 21 months, without evidence of valvular damage. Death took place, but there was no necropsy. The appearance of the colonies grown from the blood suggested that the case belonged to the subacute bacterial group.

269. Cretinism.

R. L. KNAGGS (*Brit. Journ. Surg.*, January, 1929, p. 371) defines cretinism as a condition characterized by dwarf growth associated with defective mental development. It occurs among the children of goitrous or cretinous parents in districts where goitre and cretinism are endemic, or sporadically in goitre-free districts in the children of healthy parents. Cretinism is due to the insufficient supply of the secretion of the thyroid gland and is allied to the myxoedema of adults. There are three definite and distinct conditions—endemic cretinism, sporadic cretinism, and cachexia strumipriva—the two former developing in infancy or early childhood, and the latter, which follows the removal of the thyroid, usually occurring in adult life. Cretinism may supervene after some infectious illness, such as measles or whooping-cough. Sufferers from endemic cretinism are frequently dwarfs, from forty to sixty inches in height when fully grown, with short, broad bodies. The neck is short and thick, the abdomen large and pendulous, the forehead low, broad, and sloping, and the nose flat; the eyes are small and widely separated. The legs are short and sometimes crooked, with weak, ill-developed muscles. Idiocy is an essential part of cretinism. Sporadic cretinism, unlike the endemic type, is not associated with goitre, but with a wasting or absence of the thyroid body; the outward signs are, however, very similar. It is characteristic of cretinism that the ossific centres are very late in appearing in the cartilaginous epiphyses, and the evidence of delayed endochondral ossification is well marked in the spine. The pelvis is usually very diminutive, its true conjugate being two-thirds and its breadth only half the normal dimensions. The chief features of the histology of cretinism are: a diminution in the amount of cartilage proliferation in the ossification zones, the formation of a continuous layer of bone separating the

proliferating cartilage from the marrow, and a change in the marrow from an active cellular tissue to a more or less inert fatty one. In the endemic disease the living agent is probably conveyed to the individual by contaminated food or water; in sporadic cases and in myxoedema the toxic substances may arise from the patient's natural intestinal micro-organisms. Treatment consists in the careful and continuous administration of thyroid extract, which has a very marked effect in sporadic cretinism, there being a rapid increase of stature and physical development. If this condition is treated at an early stage the general improvement is so steady that the patient may become practically normal. In endemic cretinism thyroid therapy is not so satisfactory, since, although ossification and growth are increased, there is little improvement in the mental condition.

Surgery.

270. Ambulatory Treatment of Varicose Ulcers.

L. DE GAETANO (*Il Policlinico*, Sez. Prat., January 28th, 1929, p. 113) gives an account of the technique he employs in the ambulatory treatment of varicose ulcers. The principle of this lies in directing the venous and lymphatic circulation from the superficial parts towards the deep. By encouraging the patients to walk, the muscular contractions also facilitate the return circulation; the katabolic products of the cellular elements which caused the formation of the ulcers, and are also the reason for their persistence, are at the same time removed. The technique of the method has two stages: a period of preparation and a period of apparatus. During the first of these the skin is disinfected, the eczema cured, and the ulcerated tissue stimulated to heal. The means employed are rectified benzene to cleanse the skin, alcohol acidified with acetic acid to disinfect, an anti-eczema ointment, and an ointment containing scarlet-red to stimulate the epithelial cells. This period lasts from a few days in mild conditions to three weeks in inveterate cases. In the second stage the limb is raised to a right angle with the trunk for five to ten minutes; a thin layer of sterile gauze is then applied, and finally the compressive bandage is fixed. This bandage consists of strips of plaster 2 cm. wide; it is warmed before application, and is pressed sufficiently close, each layer overlapping the previous one, beginning at the foot and ending at the knee. Béslier plaster is preferred by the author. The limb is then bandaged in Velpeau bandages. The author claims that this method is compressive and therefore differs from Baynton's, which is protective only. To complete the cure the patient is advised to walk about, so causing the blood to return through the deeper veins. The patient is seen again after five to seven or more days for the removal of the apparatus. When the strapping is removed, pus and the products of maceration are seen on the gauze, and a tendency to granulate is observable in the ulcers. The time for cure to be effected is variable. Mention is made of one patient who had rested for many months and tried innumerable remedies without avail; in less than a month he was cured by the ambulatory method, which, the author adds, is welcomed by patients who have not the time to rest or the courage to face operative measures.

271. Malignant Tumours of the Pancreas.

G. DENCKS (*Deut. Zeit. f. Chir.*, January, 1929, p. 147) remarks that, although tumours of the ampulla of Vater can be diagnosed early owing to their characteristic symptoms, operative treatment is often unsuccessful. Simple tumours are very rare, sarcoma is less rare, and carcinoma is the commonest variety found. The tumour usually projects into the bowel from a broad base; even when quite small it can occlude the bile duct sufficiently to produce severe jaundice. The origin of these tumours is doubtful. Metastasis is not common. In most cases a deep jaundice is the only disability, but difficulties in diagnosis may arise when other conditions are present, such as cholecystitis or infection of the bile ducts. An operation should swiftly follow the making of the diagnosis. The transduodenal is the usual route, and resection of the duodenum is the most radical method. Dencks has operated on eight patients; in three the tumour and metastases were so extensive that nothing could be done. Of the remaining five patients, two between the ages of 31 and 34 had sarcoma, and three between the ages of 48 and 61 carcinoma. Metastases were found in one case of sarcoma and in one of carcinoma; in both the symptoms had been present for more than eighteen months. The chief symptoms were epigastric pain, pressing and dragging in character, and worse after meals; loss of appetite; jaundice which began early, but in all except one instance showed remissions; and the invariable presence of occult blood in the stools. Loss of weight was considerable, but slight gain occurred in hospital. In Dencks's cases the tumours gave rise to no symptoms until they had reached the size of a chestnut or plum. There was no serious infection of the biliary passage. The liver and gall-bladder were both enlarged. X-ray examinations of the stomach and intestine afforded valuable help in diagnosis. In two cases the radical resection of the duodenum was performed, in two a transplantation was effected, and in one radium was inserted.

272. Acute Intussusception in Children.

P. BOHÉME (*Rev. de Chir.*, 1928, No. 8, p. 582) gives an account of nine cases of intussusception in infancy or early childhood observed during the last few years. Of these, four cases were operated on after the failure of medical treatment; three recovered and one died. In four cases the intussusception was reduced spontaneously, and of these all recovered. One patient died as a result of the failure of medical treatment, surgical intervention being refused. The symptoms were violent colicky pains, with vomiting, restlessness, the passing of a small quantity of blood, and tenderness; in most cases the tumour could be felt. Bohême states that an operation should not be undertaken until this tumour has been felt, since the other symptoms are not sufficient in themselves to justify a diagnosis of intussusception. He does not consider that an acute intussusception necessarily involves immediate surgical treatment, since one child did well who was not operated on until the sixth day. Medical treatment should first be tried, though in the series of cases reported it was unsuccessful in three out of five. In cases of failure surgical intervention is the only alternative, and affords a fairly good hope of recovery in spite of the youth of the patient.

Therapeutics.

273. Influence of Morphine on Respiration.

SINCE morphine decreases mental and physical functional activity F. P. CHILLINGWORTH and A. CANZANELLI (*Journ. Lab. and Clin. Med.*, January, 1929, p. 291) reasoned that the slowing of the respiratory apparatus accompanying its administration would limit or retard the need for oxygen and decrease the output of carbon dioxide, and hence a partly asphyxiated subject would live longer because the available oxygen would be utilized more slowly. A brief review is given of the behaviour of the respiratory centre under the influence of morphine, and the results are recorded of a series of experiments to ascertain the use of this drug to delay asphyxiation in man. The tests were made on white rats in air-tight compartments; it was found that, with proper dosage, morphine could prolong life in such conditions. It was also shown that morphine is a depressant of the respiratory centre and of all physical activity, this general depression slowing respiration by reducing oxygen consumption and by raising the oxygen and carbon dioxide thresholds. Owing to the diminution in the utilization of available oxygen, the oxygen level at which death occurs is reached later in morphinized than in untreated subjects. Since the oxygen threshold is raised by morphine, the authors believe that in cases with marked anoxaemia (pneumonia) other drugs should be used, or at least reduced doses of morphine be given, perhaps more frequently. Decreased functional activity indicates a slowing of the basal metabolic rate.

274. Treatment of Meningococcal Meningitis.

K. HOLTZ (*Arch. f. Kinderheilk.*, November 27th, 1928, p. 293), who records an illustrative case, states that the value of the intrathecal serum therapy of meningococcal meningitis is still a matter of dispute, in spite of numerous records of its success and favourable statistics. In view of the variable severity of this infection, the mortality from which even apart from treatment ranges in different epidemics from 20 to 80 per cent., statistical evidence of the value of serum treatment cannot be regarded as conclusive. Holtz records the case of a girl, aged 8, suffering from a very severe attack of meningococcal meningitis, who made a rapid and uncomplicated recovery after treatment by large doses of antimeningococcal serum (270 c.cm.) combined with injection of air (160 c.cm.) for displacing the cerebro-spinal fluid, 600 c.cm. of which were evacuated. The advantage of first displacing the cerebro-spinal fluid by air lies in the fact that it not only helps to rid the central nervous system of micro-organisms and their toxins with the associated hyperaemia, but it also enables the serum to reach the surface of the brain and the ventricles in a much more concentrated form. Early employment of the serum is an important factor in the success of the treatment. A guide for the duration of the treatment is furnished by the change in the cellular reaction of the cerebro-spinal fluid from a polymorphonucleosis to a lymphocytosis.

275. **The Maintenance Dose of Digitalis.**

As a means of ascertaining the maintenance dose of digitalis, A. W. BROMER and H. L. BLUMGART (*Journ. Amer. Med. Assoc.*, January 19th, 1929, p. 204) considered that an index of the degree of digitalization present might be better indicated by the characteristic alterations in the T-waves as seen in electrocardiograms following the administration of the drug than by estimations based on the toxic symptoms, nausea and vomiting. Accordingly they conducted a series of experiments on eight male patients whose ages ranged from 14 to 62; one of these showed auricular fibrillation and the remainder a normal sinus rhythm. None of the patients had received any digitalis preparation for at least a month, a period sufficient for complete elimination of the drug. A freshly prepared and standardized galenic tincture was used throughout the investigation. The experiments, which are fully described, showed that the daily maintenance dose of digitalis ranged from 19.8 to 28.9 minims, the average being 23.5 minims, or approximately one minim per hour. In a given individual the greatest variation was 3.1 minims. The daily maintenance dose was not apparently related to the weight of the subject or to the total therapeutic dose calculated according to the Eggleston method; it was essentially the same for all subjects regardless of cardiac lesions or of the degree of circulatory compensation. The earliest definite alteration in the T-wave occurred when an average of 54.8 per cent. of the total therapeutic dose (Eggleston) was within the body. The authors conclude that this method may be used as a quantitative index of the amount of digitalis effective within the body.

276. **Powdered Milk Preparations.**

IN reply to the assertion that evaporated milk is "dead" milk, A. ROUMR (*La Gynécol.*, November, 1928, p. 643) states that milk dried on heated cylinders still contains a sufficient quantity of ferments such as diastase and oxydases to maintain children in good health. He quotes the statistics produced at the International Dairy Congress in 1923, showing that the use of this milk in Great Britain had been accompanied by a remarkable decrease in infant mortality. Milk dried over heated cylinders at a temperature of 105° to 110° C. should contain antineuritic and antiscorbutic vitamins in ample quantity. At a temperature of 98° to 100° C. almost complete sterilization occurs, except in regard to non-spore-bearing and thermo-resistant bacteria. Cold cannot destroy pathogenic micro-organisms, and pasteurization is therefore preferable to refrigeration. Any partial deficiency of vitamins may be supplemented by a teaspoonful of fruit juice (preferably lemon juice), which contains excess of vitamins B and C. If in the case of older children there is reason to fear rickets, 10 to 20 drops of cod-liver oil should be given every twenty-four hours, or irradiated substances may be substituted. If irradiated milk-powder is given, 5 or 6 drops of an oily solution of ergosterol should be added.

Dermatology.

277. **Thallium Acetate in Ringworm of the Scalp.**

G. V. BEDFORD (*Canadian Med. Assoc. Journ.*, December, 1928, p. 660) advocates depilation with thallium acetate in the treatment of ringworm of the scalp in children, and especially in favus capitis; *it may be particularly useful in* rural districts where *x* rays are not available. After careful weighing without clothes the child is given a single dose of *thallium acetate accurately prescribed in a dosage of 1/8 grain* (8 mg.) per kilo of body weight, and administered the first thing in the morning in half a wineglass of sweetened water, *food being withheld until noon.* A daily shampoo with liquid green soap is given, with an application each night and morning of ammoniated mercury ointment (2 per cent.) or sulphur ointment (5 per cent.). *In about a fortnight depilation com*mences and is usually complete in about three weeks. Since the hair quickly begins to grow again, it is important that the *daily shampooing and applications* should be continued for at least a month to protect the new hairs against infection. In a series of twenty-one cases toxic effects occurred three *times, comprising* pain and swelling in the knees and ankle-joints, which cleared up under salicylate treatment; such toxic symptoms are more likely to occur in children approaching puberty than in younger patients. Since the powder tends to deliquesce, it should be dispensed in a glass container. M. J. ORMEROD (ibid., p. 663) describes the pharmacological and toxicological aspects of thallium, and concludes from clinical and experimental evidence that the drug is well borne by young children up to 7 or 8 years of age. *In animals the action* of the drug was found to be cumulative, acting much like lead and arsenic, with early involvement of the central nervous system, as evidenced by *apathy, tremor,* and paralyses. Metabolism is affected, and there is calcium deficiency, which probably explains the muscle cramps, but there is no evidence that permanent damage to the hair follicle results, nor that lasting endocrine disturbances ensue.

278. **Congenital Haemorrhagic Angiomatosis.**

C. H. FLANDIN and P. SOULIÉ (*Bull. et Mem. Soc. Méd. des Hôp. de Paris*, December 20th, 1928, p. 1781) report a case of hereditary haemorrhagic angiomatosis, a peculiar *familial* disease first described by Osler under the name of congenital haemorrhagic telangiectasis. The essential characters of this malady are *haemorrhages (chiefly nasal and gingival)*, followed by the appearance, especially on the face and more rarely on the hands and feet, of discrete vascular spots, *which bleed easily and progressively* become prominent. The repeated haemorrhages ultimately cause an anaemic state which is often serious. The familial and hereditary nature of the disease is markedly shown in the authors' case, since isolated appearances of the condition had been noted in four successive generations. The patient, a woman aged 54, had suffered from frequent epistaxis since her youth, and the last attack was so severe as to cause a state of syncope with extreme pallor and dyspnoea. On examination, several carmine-red, slightly raised spots were seen on the face, with a few on the fingers, lips, upper surface of the tongue, and on the conjunctivae near the border of the lower eyelids. The patient had previously noted several red spots under the nails. The haematological examination was normal, the Wassermann test being negative. Cardiac examination revealed an aortic systolic souffle, propagated to the cervical vessels and followed by a hard second sound. Attention is drawn to the red colour of the spots. In cases previously reported the tint was more cyanotic and there was evidence of venous dilatation; in the present case arterial dilatation was apparently present. According to Darier these red spots are due to a proliferation of the dermic vascular apparatus. The probable cause of the haemorrhages is traumatism, even though unrecognized; and the facility and duration of the bleeding, which is in marked contrast to the conditions over the normal skin, is due to the fineness of the skin over the spots. Since there was no alteration in the blood, the authors consider that the change was vascular rather than haemic, and that the haemorrhages are due to the direct rupture of small arterioles of abnormal calibre. The pathogeny of the disease is unknown.

279. **Atrophic Bullous Cutaneous Distrophy.**

A. PASINI (*Ann. de Derm. et de Syph.*, December, 1928, p. 1044) reports two cases of pemphigus secondary to epidermic cysts, and in each case associated with a rare papular rash which the author had never seen before. The patients were both females, their ages being 27 and 17; in one case there was a hereditary history. The papules, which were chiefly distributed on the trunk, developed slowly and did not disappear; they were of an ivory-white colour and projected 1 or 2 mm. above the surface. *In some places* they measured 15 mm. across. They were primary in origin and their appearance was never preceded by any premonitory symptoms. They were nearly always grouped around a follicular orifice, and in some cases a transitory bulla appeared at the summit. They caused no pain and never showed signs of inflammation or cicatricial character. Probably the etiological factor was some trophic change. The nails were affected.

Obstetrics and Gynaecology.

280. **Etiology of Accidental Haemorrhage.**

F. J. BROWNE and GLADYS H. DODDS (*Journ. Obstet. and Gynaecol. of the British Empire*, Winter, 1928, p. 661) record further work in the experimental induction of accidental haemorrhage (premature detachment of the placenta) in rabbits. In a previous paper Browne (*British Medical Journal*, 1926, i, p. 683) had shown that in rabbits who had received during three months intravenous injections of 1 per cent. sodium oxalate solution, and had then been mated, further injections of sodium oxalate and of an emulsion of *B. pyocyaneus* about the twentieth day of pregnancy were followed within a few hours by external accidental haemorrhage, accompanied in some cases by concealed retroplacental haemorrhage, placental thrombosis and infarction, and extravasation of blood in the myometrium. These experiments were taken to support the view that chronic nephritis is an essential predisposing cause of accidental haemorrhage. In the present paper the microscopical characters of the kidneys are described in detail; although the oxalate injections had been given for three months only, the cortex, especially in the region of the first convoluted tubes, showed very extensive fibrosis, and in many areas the tubules had all but disappeared and had been replaced by connective tissue, round-cell infiltration being conspicuously absent. In further experiments, here recorded, Browne and Dodds show that

(1) the haemorrhagic phenomena about the twentieth day of pregnancy can be induced (provided that chronic nephritis has been set up by oxalate injections before conception) by injections of *B. pyocyaneus* emulsion and of uranium acetate, or by injections of emulsion alone, or by injections of uranium acetate alone; (2) when an oxalate nephritis has not been induced the bacillary emulsion does not cause accidental haemorrhage even if acute nephritis is set up, and uranium acetate injection, accompanied by acute nephritis, is unable to induce accidental haemorrhage or placental infarction save in exceptional cases. The conclusion drawn is that the existence of an antecedent chronic nephritis is the essential factor in the production of accidental haemorrhage. It is noteworthy that in some of the animals suffering from chronic oxalate nephritis ante-partum haemorrhage occurred spontaneously during the second half of gestation, and that in all these animals the liver function (as shown by the bromsulphthalein test) seemed normal, and no morbid hepatic conditions were demonstrable after death. In these animals albumin was often absent from the urine between pregnancies and during the early part of pregnancy; it reappeared in the latter half of gestation and before the onset of spontaneous haemorrhage. The authors believe that there is a close pathological connexion between (1) placental thrombosis followed by infarction; (2) so-called utero-placental apoplexy with retroplacental haematoma and haemorrhage, and thrombosis in the uterus and broad ligaments; and (3) revealed accidental haemorrhage. Although clinically separable, these conditions are probably to be regarded as pathologically similar manifestations of maternal toxaemia, the toxins acting primarily on endothelium; the chronic nephritis operates by interfering with the excretion of such toxins, or possibly by interfering with a physiological metabolic function of the kidneys.

281. Prognosis in Carcinoma of the Ovary.

E. ALFIERI (*Ann. di Ostet. e Ginecol.*, January 31st, 1929, p. 1) compares the records of incidence, operability, and prognosis of carcinoma of the ovary furnished by the University clinic at Milan with those obtained elsewhere, and deplores the fact that the importance of early diagnosis has not received the same degree of recognition in the case of carcinoma of the ovary as in that of uterine cancer. He states that 70 to 80 per cent. of malignant ovarian tumours are carcinomatous; that about 7.5 per cent. of patients admitted to gynaecological clinics suffer from ovarian tumours, of which 20 per cent. are malignant; and that, although carcinoma of the cervix is almost four times as frequent as ovarian carcinoma, the latter is as common as carcinoma of the body of the uterus. At the time when hospital or specialist treatment is sought the prospect of cure in the average case of carcinoma of the ovary is certainly not better than in the average case of cervical cancer, and considerably less than in corporeal cancer; this is attributed to the slightness of the early symptoms, to the tumour being inaccessible to simple abdominal operation, to bimanual examination being apt to be neglected or too long deferred, and to a common reluctance to open the abdomen in cases of cystic ovarian tumours which have not yet been proved to be increasing or to produce symptoms. The proportion of inoperable cases encountered by the author and others is about 50 per cent., and the primary operative mortality about 15 per cent.; five years' cures after operation number from 10 to 20 per cent. Alfieri concludes that better results in treatment of ovarian carcinoma cannot be secured until it becomes the rule for operation to be undertaken promptly in all cases of ovarian tumours in which there is no contraindication on grounds of general health. Although four-fifths of tumours are benign, they are liable to serious complications, such as adhesion, torsion, apoplexy, necrosis, suppuration, and rupture.

232. Pregnancy after Portes's Operation.

LÉVY-SOLAL, LAENNEC, and DELARUE (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, December, 1928, p. 918) describe the case of a woman, aged 27, with general pelvic contraction, whose first labour had been terminated by craniotomy, and whose second labour, at term, was characterized, after nineteen hours' "trial," by pyrexia and by fetor of the liquor amnii. The operation of Portes-Caesarean section, followed by suture of the abdominal wall with the stitched uterus left in the exteriorized position, was performed, in view of the manifest signs of infection; the uterus was returned to the abdomen at a second operation thirty-one days later. The next pregnancy took a normal course and was terminated by Caesarean section at the beginning of labour, three years after the Portes operation. The old uterine scar, which was macroscopically satisfactory, was excised and proved histologically to be of normal character. PORTES and J. SEGUY (*ibid.*, p. 921) describe a case of spontaneous delivery at nine months of a living infant, weighing 2.25 kilograms, in a woman in whom Portes's operation had been employed four years previously.

Pathology.

283. Susceptibility to Infections and Capacity to Produce Antitoxin.

C. ZOELLER (*C. R. Soc. de Biologie*, November 23rd, 1928, p. 1578) maintains that susceptibility to disease and the capacity to produce antitoxin are not necessarily identical in the same subject. The following four combinations may occur. (1) Both the susceptibility and the capacity to produce antitoxin may be increased; there are subjects who are susceptible to the disease but can easily be protected by inoculation. (2) The susceptibility may be heightened, while the capacity to produce antitoxin is feeble or absent; these are subjects who are susceptible to the disease, liable to relapses, and refractory to inoculation. (3) Susceptibility may be weak or absent, while the capacity to produce antitoxin is enhanced; these are more or less insusceptible subjects who readily undergo spontaneous or artificial immunization. (4) Susceptibility may be slight and the capacity to produce antitoxin be weak or absent; these subjects are unsuitable as donors and are relatively protected owing to their low degree of susceptibility. The first group comprises persons who have had a typical attack of diphtheria, but who are subsequently shown by the Schick reaction to be quite capable of acquiring immunity to the disease. The second group consists of hypersusceptible individuals, the frequency of whom in a community restricts the efficacy of a method of immunization. In addition to human subjects, the third group contains animals like the guinea-pig, which has a considerable capacity to form antitoxin, but has no susceptibility to spontaneous diphtherial infection. The fourth group includes very young children, who are alike unable to contract diphtheria and to become immunized, as well as persons who have undergone passive immunization.

284. Distribution of Growth in the Long Bones.

E. BERGMANN (*Deut. Zeit. f. Chir.*, January, 1929, p. 303), by measuring the distances between the metaphyseal lines of calcification, has shown that in the growth of the long bones the greatest addition to length is from the distal cartilage of the femur, an amount almost double that derived from the proximal epiphysis of the femur. In the case of the tibia the distal and proximal zones of growth are about equal, and in the arm the growth is about three times as great in the epiphyseal centres most distant from the elbow-joint. Observations on the lengthening of the leg of a child suffering from tuberculosis of the knee-joint suggested that the diseased condition had produced a local hyperaemia which had increased the rate of growth. Not only has the diaphysis a pathological increase of growth, but the ossification of the epiphyses is much more advanced than on the healthy leg, so that the diseased knee appeared to belong to a person a year older. This hastening of ossification is shared by the patella; the patella of the diseased knee is twice as ossified as the healthy patella.

285. The Secretory Function of the Stomach.

IT is a well-known fact that many cases of disease of the gall-bladder are accompanied by gastric hypoacidity. In order to find the actual relation between the two phenomena S. O. BADYLKES (*Tezapevtichesky Archiv*, vol. vi, Fasc. 6, 1928, p. 534) performed seventy-one experiments on the isolated stomachs of dogs, and arrived at the following conclusions. Foreign bodies and inflammation of the gall-bladder cause a marked diminution of the secretion and of the acidity of the stomach, and a slight decrease of the duration of the secretion. The secretory curve and the digestive power of the gastric juice remain unaffected; in the stomach isolated as in the Heidenhain experiment there is an increase of the digestive power of the gastric juice. The diminished secretion in cholecystopathies is caused by an inhibition through the sympathetic nervous system. Following short acute irritation of the gall-bladder, a possibly compensatory increase in the gastric secretory activity could be noted after the period of initial inhibition.

286. Urinary Infection by Morgan's Bacillus I.

A. JERVELL (*Norsk Mag. f. Laegevid.*, December, 1928, p. 1245) records two cases in women, aged 27 and 35 respectively, in whom Morgan's bacillus I was cultivated from the urine, and in the younger patient from the blood and faeces as well. The clinical symptoms did not differ from those of ordinary *B. coli* infections of the urinary tract. In both cases the serums showed a high agglutination titre, and serological identity of the two strains was shown by agglutination, absorption, and complement-fixation tests. These cases support the view that Morgan's bacillus is closely related to *B. coli* pathogenically.

FELAMINE

BRAND
SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

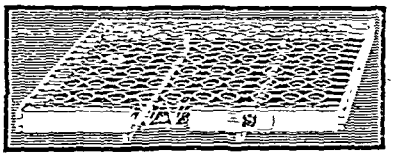
Announcing
THE 1929 STAPLES MATTRESS

BY APPOINTMENT
Wire Mattress and
Bedstead Manufacturers
to H.M. THE KING

Even *more* luxurious is the 1929 Staples Mattress—deeper springs, softer cords and long end springs. Little refinements for the fastidious everywhere. The resilient Staples springs hold the spine straight and the vital organs of the body undistorted the whole night through. Muscles are naturally relaxed and automatically the nervous system obtains complete rest for the duration of sleep. Always pre-eminent for Luxury the 1929 Staples stands in a class by itself—Built only for those who demand the Best—More costly to produce but the PRICE REMAINS THE SAME.

Staples Mattress, 3' 99/-, 4' 6" 118/6.
There is *also* the
Staples No. 20, 3' 82/6, 4' 6" 95/-; *Staples No.* 30, 3' 63/-, 4' 6" 70/-



STAPLES MATTRESS

"The finest mattress made"

A visit to our works showroom at Staples Corner, Cricklewood, is well worth while. The "Commonsense Health" Mattress Booklet and new 1929 Catalogue of Staples Bedstead Designs, are sent post free on application to Dept. 4.

Tel. No.: GERRARD 3185

45, OXFORD STREET,
2, RATHBONE PLACE,
LONDON, W.1.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE. *Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.*

MEDICAL REPORTS. *Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.*

HOME TESTS ARRANGED FOR DOCTORS AND PATIENTS. *Medical prescriptions made up to the minutest detail.*

309, OXFORD ST., W.1.
(Midway between Oxford Circus and Bond St.)
Tel.: Mayfair 1380/1718.

NORVIC

BLUE CARTON Crêpe Bandages for Varicose Veins

They combine warmth and support.

Exceptionally durable and elastic. The Flesh Colour is practically invisible under Silk Stockings.

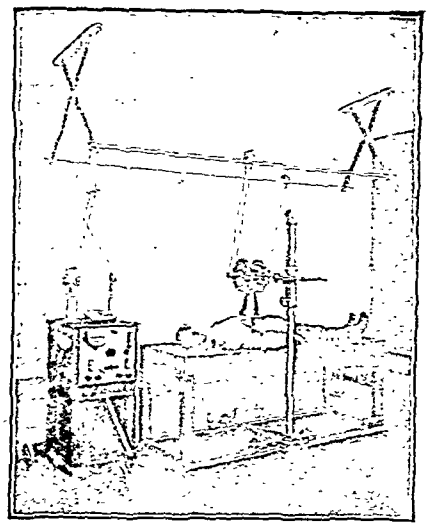
Prices: 2 in. 1/6, 2½ in. 1/11, 3 in. 2/3, 3½ in. 2/8, 4 in. 3/-.

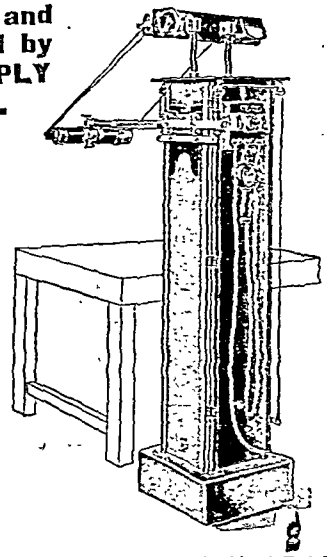
70% WOOL QUALITY

Stocked by all Chemists and Druggists, BOOTS 800 BRANCHES, TIMOTHY WHITE LTD., TAYLOR'S DRUG STORES; and PARKES' CHEMISTS LTD.

NEW AND IMPROVED X-RAY APPARATUS

Made and Guaranteed by The MEDICAL SUPPLY ASSOCIATION, LTD.





A technical representative will be sent to discuss these instruments on receipt of a definite appointment.

THE "ECONOMICAL" X-RAY OUTFIT

Call and see it in operation.

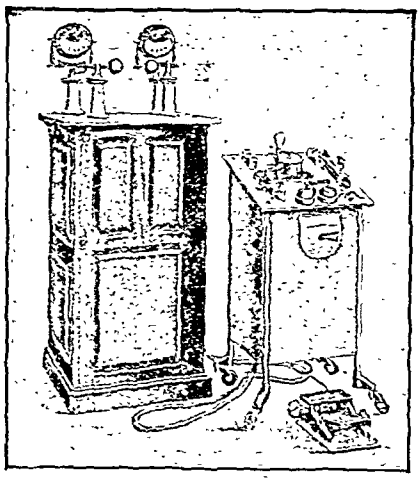
As the "Emesay," but fitted, in addition, with complete equipment for Radiographic Department as illustrated, and including: Coolidge X-ray Tube, Radiographic Couch, complete Tank Development Outfit, Fluorescent and Intensifying Screens, Compression Gear, Overhead High-tension Aerials, Negative Viewing Desk, etc.

Best British make, therefore no importation tax.

PRICE as illustrated and described—

For use on Alternating Current.....£206 10 0
" " Direct Current £251 10 0

For full particulars send for CATALOGUE No. B34.



THE "PRACTITIONER'S OWN" X-RAY APPARATUS

brings radiography within the reach of every doctor. Simple to operate, constant results, perfect protection, compact design. Fitted with: Technique Director, which automatically gives the setting of the simple controls for radiographing any part of the body; Adjustable Tube-arm; Automatic Time Switch; Oil-insulated High-tension Transformer; Milliampere-meter, etc. Supplied for portable or consulting room requirements.

Best British make, therefore no importation tax.

PRICE for use on Alternating Current..... .... £123
" " Direct Current £153

For full particulars send for CATALOGUE No. B33.

The New RADIO-METRIC X-RAY APPARATUS

For rapid Radiography, Radioscopy, Radiotherapy.

A Pillar of Strength. A Marvel of Simplicity.

Now fitted with: Independent Switch Table, Automatic Time Switch, Independent Filament Transformer, Oil-insulated High-tension Transformer, Spherical Spark Gap, Ampere-meter, Milliampere-meter, Foot Switch, Auto-transformer, Regulation Kilo-volt Scale, Technique Director, etc. The whole designed and guaranteed to operate the Coolidge Radiator Tube up to its MAXIMUM CAPACITY.

GUARANTEED OUTPUT through the X-ray Tube.

4 HORSE-POWER OF ELECTRICAL ENERGY or 3040 WATTS!!!

Best British make, therefore no importation tax.

Price for use on Alternating Current £195
" " " Direct Current £250

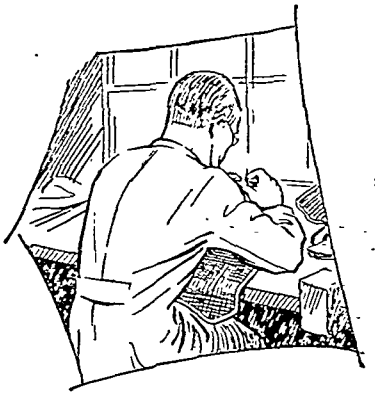
SALTAIR

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.



Craftsmanship

IT is essential in the manufacture of all Surgical Appliances that the greatest care and accuracy must be taken.

We make no stock patterns, so that every Appliance made by us receives individual attention to detail by highly experienced workmen.

In all our work the two main objectives are

Accuracy to Medical Instructions.
Maximum Comfort for the Wearer.

These can only be obtained, not by experience alone, but by experience linked with the high standard of craftsmanship that characterises all our products.

THOSE OVERDUE ACCOUNTS!!

We have sent to us a far higher percentage of incurable cases (bad payers) than any other Professional class.

We also get a far higher percentage of cures (cash) than any other Professional body.

The originals of the following testimonials may be seen by any responsible person at this office:

Dear Sir,

Thank you for your cheque £6 6s. received on February 1st.

I should like to record my appreciation of the work you have done for me up to date. I have given you some very difficult cases to deal with, which you have carried through in a most tactful and successful manner.

Yours faithfully,
L. D.——

Dear Mr. Watson,

re Mrs. ——, of 5, ——

No doubt in response to your letter, I have to-day received a cheque for £105, the amount of fees due to me by this patient. Many thanks for your services I was unable to get any reply to my letters.

Yours faithfully,
E.——

Let us collect your overdue fees "Without Offence."

The Twenty h.p. Rolls-Royce

"The 20 h.p. Rolls-Royce is noteworthy because of its design, quality and performance. These are, literally, well nigh perfect and its behaviour is the proof. Acceleration and top-gear performance rob the driver of handling his gear lever out of necessity—gear changing, in fact, must be a pastime, not a duty, when it is undertaken. But even when such unnecessary operations are undertaken the driver's ear will be left unaware of his action. Acceleration is as smooth as velvet and as powerful as the iron hand under the proverbial glove. Steering is light and true, and the brakes as faultless in effect as any that designers of the future will ever invent.

Rolls-Royce makers breed their car for perfection—or rather, since they are the first people to say their cars are not perfect, "quality" is the keynote of their production. With perfection as their goal, this firm is in the forefront of the race."

EATAN

Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-irritant.

Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 12/- bottles.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, *persons suffering from incipient nervous and mental disorders*, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for *Diathermy and High Frequency treatment. It also contains Laboratories for* biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy *is a feature of this branch, and patients are given every facility for occupying themselves* in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 Northampton), who can be seen in London by appointment.

Chemistry, Physics, and Biology Labs.
MANCHESTER TUTORIAL COLLEGE,
327, Oxford Road, Manchester.

Required by the Government

of SOUTHERN RHODESIA, an ASSISTANT SCHOOLS DENTAL SURGEON, for school children. Salary per annum, plus local of £150 per annum. Passage to Salisbury will be provided. Applicant must be under 32 years of age, should be single, and must hold Dental degree or diploma registrable in Great Britain, but dentists registered under the Dentist Act, 1921, will not be accepted.

Private practice not allowed.

Application should be addressed to the High Commissioner for Southern Rhodesia, Crown House, Aldwych, London, W.C.2, from whom full details of the duties and of the terms of the appointment can be obtained.

Hendon Urban District Council.

COMBINED POST OF RESIDENT MEDICAL OFFICER AT THE ISOLATION HOSPITAL AND ASSISTANT MEDICAL OFFICER FOR GENERAL PURPOSES.

Applications are invited for the above post. The successful candidate will be required to reside at the Isolation Hospital (at present under construction) and to perform the duty of Resident Medical Officer, together with other duties in connection with the Council's Maternity and Child Welfare and School Medical Services, and generally to assist the Medical Officer of Health.

Candidates must possess a Public Health qualification and should have had Fever Hospital experience.

The salary is £500 per annum, rising by annual increments of £25 to £600 per annum, with board, lodging, and laundry. If the officer appointed takes up duty before the Hospital is completed an allowance at the rate of £150 per annum will be made in lieu of board and lodging, etc.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The successful candidate will be required to pass a medical examination.

Applications, on forms to be obtained from the undersigned, together with copies of not more than three recent testimonials, to be sent to the undersigned not later than April 6th.

Dated this 4th day of March, 1929.

Town Hall, Hendon, N.W.4. LEONARD WORDEN, Clerk to the Council.

Hendon Urban District Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the above post. The duties will be mainly in connection with the Council's Maternity and Child Welfare and School Medical Services, but may include other duties under the direction of the Medical Officer of Health.

Candidates must possess a Public Health qualification.

The salary is £600 per annum, rising by annual increments of £25 to £700 per annum.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The successful candidate will be required to pass a medical examination.

Applications, on forms to be obtained from the undersigned, together with copies of not more than three recent testimonials, to be sent to the undersigned not later than April 6th.

Dated this 4th day of March, 1929.

Town Hall, Hendon, N.W.4. LEONARD WORDEN, Clerk to the Council.

University of Durham College

OF MEDICINE,
NEWCASTLE-UPON-TYNE.

PUBLIC HEALTH LABORATORIES and BACTERIOLOGICAL DEPARTMENT.

Applications are invited for the post of Whole-time ASSISTANT. Applicants must be registered medical practitioners (male), with experience of Public Health Bacteriology and Clinical Pathology. In addition to work in the Public Health Laboratories, the Assistant will be required to take part in teaching.

Appointment will be probationary in the first in , from £350 to £ .

of three recent testimonials, should be submitted not later than March 19th to the Registrar, University of Durham College of Medicine, Newcastle-upon-Tyne.

Sculcoates Union (Hull).

APPOINTMENT OF NON-RESIDENT SENIOR MEDICAL OFFICER (Male).

The Guardians of the Poor of the above-named Union invite applications for appointment of a full-time non-resident Senior Medical Officer at the Institution, Beverley Road, Hull. Applications will be considered from fully qualified persons between and including the ages of 30 and 45 years only.

The number of inmates is about 900, of whom approximately 300 are sick.

The salary will be at the rate of £700 per annum, rising by annual increments of £50 to a maximum of £800 (no bonus); there are no other emoluments attached to the office, and the salary is inclusive of all fees which might otherwise be received by the Medical Officer. The person appointed will be required to repay to the Guardians all fees received by him under the Lunacy Acts.

The person appointed must provide his own residence at a place to be approved by the Guardians, and must have held a post in a General Hospital or in a Poor Law Infirmary. He may, to some extent, after April 1st, 1930, be subject to the instructions of the Medical Officer of Health for the City of Hull.

The attention of candidates who are not already in the Poor Law Service is drawn to the provisions of the Local Government Bill affecting transferred Officers on the abolition of Boards of Guardians.

The above-mentioned salary is inclusive of a payment of £10 per annum in respect of Vaccination duties, and £25 per annum in respect of duties as Medical Officer of the Cottage Homes, Hessle, near Hull (approximate number of children 120).

The appointment is subject to the provisions of the Poor Law Officers Superannuation Act, 1896.

The Infirmary is not under separate administration. The staff comprises the Senior Medical Officer, a Resident Assistant Medical Officer, a Visiting (Operating) Surgeon, a Superintendent Nurse, and 65 other Nurses.

Particulars of the duties will be sent on request. Applications, setting out qualifications, dates of registration, experience, etc., together with copies of not less than three recent testimonials, must be sent so as to be received by me not later than the 23rd instant.

Selected candidates will be notified when and where to attend.

12, Harley St., Hull. W. BARROW, Clerk to the Guardians.

March 6th, 1929.

Bedfordshire County Council.

ASSISTANT MEDICAL OFFICER (Woman).

Applications are invited for the above appointment. The officer appointed will be required to assist chiefly in the School Medical and Maternity and Child Welfare Services of the Council. The officer, who will be under the direction of the County Medical Officer of Health, will be required to perform such other duties as the Council may direct.

Applicants must be registered medical practitioners, possess a Diploma in Public Health, and have had experience in the branches of Public Health referred to. The person appointed will be required to devote the whole of her time to the duties assigned to her, and not to engage in private practice.

Salary £600 per annum, together with a travelling allowance of £170 per annum, the appointment to be subject to three months' notice to be given by either side at any date.

Further particulars can be obtained from the County Medical Officer, Shire Hall, Bedford.

Applications, stating age, qualifications, and previous experience, accompanied by copies of three recent testimonials, and endorsed "Assistant Medical Officer (Woman)," should be sent to the undersigned not later than Monday, March 18th.

Shire Hall, Bedford. J. B. GRAHAM, Clerk of the County Council.

February 25th, 1929.

Romford Union.

OLDCHURCH HOSPITAL.

RESIDENT SECOND ASSISTANT MEDICAL OFFICER.

The Guardians of the Romford Union invite applications for the appointment of a Second Assistant Resident Medical Officer (male) at their Oldchurch Hospital, Romford, which has a present accommodation of 550 beds.

Applicants must be single, and preference will be given to one who has held the position of House Surgeon or House Physician in a General Hospital.

The appointment is governed by the regulations laid down in the orders of the Ministry of Health.

The salary will be at the rate of £250 per annum, subject to deductions under the Poor Law Officers Superannuation Act, 1896, with furnished apartments, maid, rations, and laundry.

Forms of application may be obtained from the undersigned upon receipt of a stamped addressed foolscap envelope, and must be returned not later than Monday, the 25th instant.

By Order,

Union Offices, Romford. R. H. MASON, Clerk to the Guardians.

APPOINTMENTS.—Contd.

The Gloucestershire Royal INFIRMARY AND EYE INSTITUTION, GLOUCESTER. (145 Beds.)

Applications are invited for the post of SECOND HOUSE SURGEON (male). Salary £100 per annum, with board, residence, and laundry. (Four resident medical officers.) The appointment is for six months, which may be extended for similar periods by re-election from time to time.

Applications, stating age, qualifications, and nationality, with copies of not less than three recent testimonials, must be received by the undersigned not later than Wednesday, March 20th. The elected candidate will be required to enter upon his duties at once.

F. J. SYMONS,
March 1st, 1929. Secretary.

Chester Royal Infirmary. (211 Beds.)

Applications are invited for the appointment of HONORARY ASSISTANT PHYSICIAN, vacant by *the resignation of Dr. N. T. GLYNN.*

Candidates must be Graduates in Medicine of a University in the United Kingdom or a University within the Empire whose degrees have been recognized by the General Medical Council as entitling to registration in the *Medical Register* of the United Kingdom.

Applications, stating age and qualifications, and with copies of not more than three testimonials, should be delivered addressed to the Chairman, Board of Management, Royal Infirmary, Chester, on or before Wednesday, the 27th instant. The successful candidate will be required to reside within three miles of Chester *Cross.*

Canvassing is prohibited.

J. ROWSE MITCHELL,
March 5th, 1929. Secretary.

Manchester Royal Infirmary.

RESIDENT SURGICAL OFFICER.

The Board of Management invite applications for the above appointment, which will become *vacant on June* 1st. Applicants must not be less than 25 years of age. They must be registered and hold a Medical and Surgical qualification.

The appointment is for twelve months, renewable for a further period of *one year*, subject to the provision of the By-laws as to notice. Salary £200 per annum, with allowance for laundry.

Full information is obtainable *from the undersigned*, to whom applicants *must send* twelve copies of their application and *testimonials* by *Wednesday, April* 17th.

By Order,
FRANK G. HAZELL, Gen. Supt. & Sec.

Derbyshire Hospital for Sick CHILDREN.

Applications are invited for the posts of (1) HONORARY PHYSICIAN and PATHOLOGIST; (2) HONORARY OPHTHALMIC SURGEON; (3) HONORARY SURGEON (Ear, Nose, and Throat), on the staff of the above Hospital, from *duly* qualified practitioners. Such applications should be accompanied by three *testimonials* and sent to the undersigned on or before Tuesday, March 19th. The election will take place at the *Hospital* on Tuesday, March 26th, at 3 p.m.

ARTHUR N. WHISTON,
25, St. Mary's Gate, *Derby.* Secretary.

Montagu Hospital, Mexborough, YORKS.

Applications are invited for the position of HOUSE SURGEON (lady) at the above Hospital (64 Surgical beds). Ten Maternity beds are also shortly to be brought into commission. Commencing salary £120 per annum, with board, residence, etc.

The position will become vacant on April 18th, and the successful candidate will be required to take up her duties on or about that date. One month's holiday will be allowed each year.

Applications, stating qualifications, should be addressed to the undersigned so as to be received not later than Thursday, March 28th.

DONALD WILSON, Secretary.

Chelmsford and Essex Hospital.

RESIDENT MEDICAL OFFICER

Applications are invited for the post of Resident Medical Officer. The appointment is for twelve months. Salary £150 per annum with board and residence.

Applications, with copies of three testimonials, to be sent to the undersigned, not later than March 25th, to Chelmsford, on or before Saturday, March 23rd.

R. G. MORRISH, Secretary.

City of Leeds.

ASSISTANT RESIDENT MEDICAL OFFICER, KILLINGBECK SANATORIUM.

Applications are invited from registered medical practitioners (male) for the post of Assistant Resident Medical Officer at the Tuberculosis Sanatorium, Killingbeck (220 Beds). Applicants must be unmarried, and preference will be given to those who have held previous Hospital appointments.

The appointment will be for one year at a salary of £250 per annum, with board, residence, and laundry.

Applications, stating age and experience, together with copies of three recent testimonials, endorsed "Tuberculosis Officer," should be delivered to the Medical Officer of Health, 12, Market Buildings, Vicar Lane, Leeds, not later than the first post on Saturday, March 23rd.

Leeds. THOS. THORNTON,
March 11th, 1929. Town Clerk.

The London County Council

invite applications for appointment as EIGHTH ASSISTANT MEDICAL OFFICER (male) in the MENTAL HOSPITAL SERVICE. Candidates must be under 35 years of age and be registered to practise both in medicine and surgery in England. Salary £300 a year, rising by annual increments of £25 to £400 a year, plus fluctuating temporary additions, making the total commencing remuneration approximately £423 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly) if required to be resident. Candidate appointed
the Asylums Officers
Form of application,
are given, can be obtained from the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1. Completed applications must be received by Thursday, March 21st. Canvassing disqualifies.

Borough of Reigate.

APPOINTMENT OF MEDICAL OFFICER AT THE MATERNITY AND CHILD WELFARE CENTRE.

The Town Council invite applications from men and women medical practitioners for the above appointment for one year as from June 1st next. The salary will be after the rate of £150 per annum.

The duties, which must be strictly adhered to, comprise attendance at two sessions of two hours each on Tuesday and Thursday afternoons from 2.30 to 4.30 at the Health Centre in connection with Infant Welfare; and one session of two hours each month, on Wednesdays, for Antenatal work, commencing at 2.30. The Medical Officer to arrange for a Locum Tenens in the event of his or her inability to attend.

The other duties and conditions attaching to the appointment can be obtained upon application to the undersigned.

Sealed applications, marked "Medical Officer —Infant Welfare Centre," should be sent to the undersigned at the Municipal Buildings, Reigate, not later than Monday, April 15th.

Dated this 6th day of March, 1929.

By Order,
ALFRED SMITH, Town Clerk.

(400 Beds.)

A HOUSE PHYSICIANCY.

A vacancy will arise on April 1st. Candidates are desired to send in applications forthwith. Salary at the rate of £125 per annum. Preference to candidates with Hospital experience. Applications to—

HARRY JOHNSON,
March 8th, 1929. House Gov. & Sec.

Coventry and Warwickshire Hospital, Coventry.

A vacancy having arisen for an HONORARY PHYSICIAN on the Staff of the *above-named Hospital*, applications are invited for the post.

In conformity with the Laws of the Institution, candidates must hold the Degree of Doctor in Medicine of a British or Irish University, or be Members or Fellows of the Royal College of Physicians of England, Edinburgh, or Ireland.

Candidates shall be resident in the City of Coventry, or within six miles thereof, or shall take up their residence within that radius within six months from date of appointment.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Applications, with original testimonials, and registration certificates, must reach the undersigned on or before April 8th.

Candidates will in due course receive notice of their eligibility or otherwise from the Secretary, and after receipt of such notice eligible candidates are at liberty to send through the post printed copies of their application and testimonials to the Governors of the Hospital, a list of whose names and addresses will be furnished by the Secretary.

No such application or copies of testimonials shall be sent until receipt of such notification from the Secretary.

By Order of the Committee,
(Miss) R. HOOPER,
March 15th, 1929. Secretary.

The Middlesex Hospital, W.1.

SENIOR RESIDENT ASSISTANT ANÆSTHETIST.

Applications are invited from qualified registered medical practitioners for the above post, vacant on April 1st until the end of December, 1929.

The appointment would be of value to gentlemen intending to specialise in anæsthetics.

The holder is eligible to apply for re-appointment for further periods of 12 months from January in each year.

Candidates must show that since qualification they have taken steps to acquire experience in the administration of anæsthetics.

Board and residence are provided and salary at the rate of £120 per annum.

During his term of office the holder may not take any other Hospital appointment, nor engage in practice outside the Hospital.

Applications, together with testimonials, should be forwarded not later than 12 noon on Monday, March 25th, to the undersigned, to whom prospective candidates should apply for a copy of the rules governing the appointment.

S. R. C. PLIMSOLL, Secretary.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {178 178

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

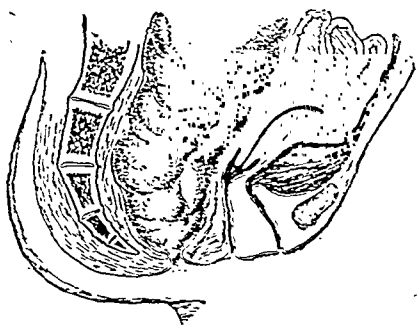
Good house available (professional rooms, 2 sitting, 3 bedrooms, dressing and bathrooms, etc., garden and garage) on rental at £50 p.a. Premium 2 years' purchase. Excellent prospects of increase.
3. LONDON, WEST.—PARTNERSHIP.—A half share in an old-established mixed general Practice. Average income for the last three years about £4,000. Panel of 3,250. Fees 2/6 to 7/6, visits 3/6 to 10/6, and a few at 21/-. About 30 midwiferies at from 3 to 10 guineas. Convenient house in good position. Held on lease (with no ground rent) with 25 years to run. Price £1,650. Premium £4,000. Must be Scotch or English.
4. CORNISH RIVIERA.—In a small but rapidly growing town (pop. 5,000—6,000) on the Coast, an old-estab. PRACTICE producing last year over £1,000, *including appts. and panel of 550 to 600.* Opposition weak. Delightful residence, standing in own grounds of 1¾ acres (croquet and tennis lawns, etc.) and eminently suitable for Resident Patients, which Vendor has been in the habit of taking. Contains professional rooms, 4 reception, 9 bedrooms, 2 bathrooms, etc. Water and electric light. Garage. Price for freehold £4,000. Prem. £1,500.
5. HOME COUNTIES.—PARTNERSHIP.—A three-eighths share (with increase later) in a very well-established mixed-class Practice, producing about £3,000 p.a. (including panel of 1,500), situated in a desirable residential district. Fees from 3/6 to 21/-. Suitable accommodation available. Ingoing Partner should be between 30 and 35, and preferably hold University degree. Premium 2 years' purchase.
6. LONDON, NORTH.—PARTNERSHIP.—A ONE-THIRD SHARE, to commence with, *in a very old-established mixed general Practice.* Income approximately £3,400, including appts. and panel of over 3,000. Surgery fees 2/- upwards, visits 3/- upwards. If unmarried, ingoing Partner could reside with senior; otherwise, suitable house available. Premium 2 years' purchase, half by arrangement.
7. LONDON, SOUTH-WEST.—Within three miles of Charing Cross.—PARTNERSHIP.—A half share, with succession to the whole in about two years, in a very old-established non-panel Practice, held by Vendor 26 years. Steady average income of £2,300. Surgery fees 2/6 and 3/6, visits mainly 5/- and 7/6. Very little midwifery. Good house, in main road, with garden. Held on lease, with nearly 15 years to run, at a rental of only £55 p.a. Premium 2 years' purchase. Very good scope for increase.
8. KENT.—COUNTRY PRACTICE, *within six miles of the Coast.*—Old-established mixed general Practice. Income for past twelve months £1,672, including appts. about £60, and panel of over 700. Fees 3/6 to 21/-. Not much midwifery 2 to 7 gns. Good house, with 2 reception, 5 bedrooms, etc. Large garden and orchard. Garage for 2 cars. Price for freehold £1,350. Sport of all kinds, and schools within reach. Premium £2,250.
9. PARTNERSHIP.—SOUTH COAST.—In a fashionable watering-place, *the two-thirds share is for disposal in a mixed Homœopathic and* Allopathic (roughly half and half) good-class non-dispensing, non-panel conection, in which there is a certain amount of surgery, and ingoing partner should be an operating surgeon. Receipts average over £3,600 p.a. Fees up to 10/6. Very little midwifery. Large and suitable maisonette available, with ample accommodation, in excellent position. Garage. Rent, on lease, £250 p.a. Premium for share 1½ years' purchase
10. PARTNERSHIP.—Within 3 miles North-West of Charing Cross.—The half share of an old-established middle and working-class Practice, averaging about £2,100 p.a., including panel of 1,300. Visits 2/6 to 10/6. House contains, in addition to professional accommodation, 2 reception, 2 bedrooms, bathroom, kitchen, etc. Small garden. Net rental, on lease, about £60 p.a. Premium 2 years' purchase.
11. HAMPSHIRE.—PARTNERSHIP.—Third share of an old-established unopposed Country Practice, in very pretty district within a few miles of a large town, and producing nearly £2,500 p.a., including appointments £130, and panel of 1,520. Visits 5/6 to 21/-. Mids. 2 to 10 gns. Large house (having eight or nine rooms, with garden, etc.), which must be purchased, or ingoing partner could reside in rooms until a smaller one becomes available. Premium 2 years' purchase, half down and balance in 12 or 18 months.
12. KENT.—Old-established Country PRACTICE, situated in very favourite locality within 5 miles of the coast. Income for past 12 months £1,050. Surgery fees 3/6 upwards, visits 5/- to 21/-. Poor Law appt. and panel of about 380. Attractive commodious house, with separate professional rooms. Small garden. Price £1,800. Premium £1,500.
13. PEAK DISTRICT.—Old-established mixed general Country PRACTICE situated in very delightful district, and offering scope. Average income about £1,000, including Poor Law appt. and panel of 650. Fees 3/6 to 10/6. Good house, on lease, rent £84 p.a. Excellent schools within reach. Premium 1½ years' purchase.
14. HOME COUNTIES.—GROWING COUNTRY DISTRICT.—Old-established mainly middle and working-class PRACTICE. Income for the last year £550, with ample scope for increase. Fees 2/6 to 7/6. Little midwifery. Good freehold house, price £1,500, part on mortgage. Sport of all kinds. Knowledge of refractions advantageous. Premium £850.
15. HERTS.—PARTNERSHIP.—A one-third share (and up to one-half in two years' time) is offered in an old-established mixed general Practice, averaging about £2,000 p.a., with good scope. Non-panel at present, but ingoing partner should undertake this work. Fees 3/6 to 7/6, a few at 15/-. Little midwifery 3 to 10 gns. Suitable house can be bought. Sport of all kinds. Premium 2 years' purchase.
16. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Long introduction.
17. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement if necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
18. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — *In a large* Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.
19. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, and good professional rooms and usual offices. Hot water supply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
20. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good and commodious house, with nice garden. Can be rented on lease at £75 p.a. Garage for 3 cars. Premium 1½ years' purchase, part by instalments.
21. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of about 2,200. Fees 2/6 to 7/6. Midwifery from 3 gns. (about 40 cases yearly). Moderate expenses. Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden. Brick-built garage. Premium £4,500.
22. CHANNEL ISLANDS.—Old-established general PRACTICE. Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery rebated. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools. Price for practice and house £3,000.
23. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE. Gross cash receipts for immediate past 12 months £657, including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. Price for freehold £1,200. Premium 1½ years' purchase.
24. LANCS.—In a rapidly growing good-class suburb of large town (pop. nearly 200,000), a very old-estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Union (£52, with prospect of increase shortly) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and panel work is attached. Private residence contains 2 reception, 3 bedrooms, bathroom, etc., and small garden. Both Vendor's properties. Price £1,750, £900 on mortgage, or would be rented. Prem. 1½ years' p.
REQUIRED.—MEDICAL OFFICER for Cable Company. Salary £500 p.a., all found. Three years' engagement. First-class out and home. Must be of British nationality and under 30 years of age. Sail end of March. Personal application preferred.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

The Menace of the Overloaded Bowel



always present, easily becomes serious in women. It causes interference with the pelvic circulation and tends to produce congestion of the uterus, not infrequently followed by functional disorders, producing dysmenorrhœa, menorrhagia, and even inflammatory conditions.

AGAROL Brand Compound gives relief and frequently permanently restores the functional activity of the colon. One tablespoonful before retiring, gradually decreased as improvement takes place, is especially well adapted for the treatment of constipation in women, because of the gentle action of Agarol Brand Compound and absence of irritation from its use.

A liberal trial quantity at the disposal of physicians.

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

FRANCIS NEWBERY & SONS, LTD.

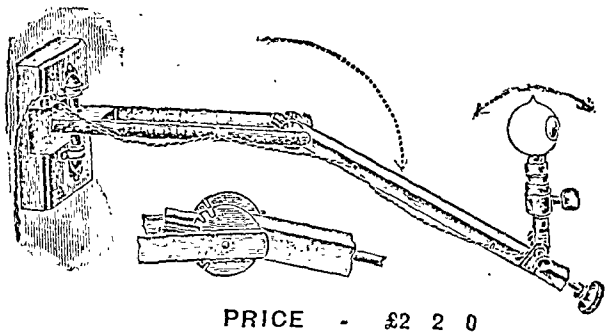
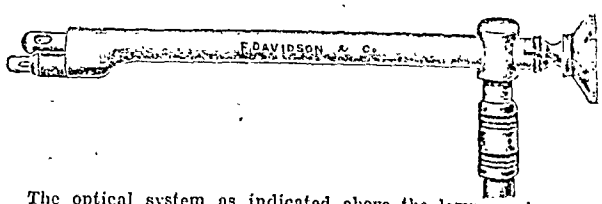
THE "DAVON" BRACKET.



PRICE - £2 2 0
Target-frosted Bulb - 3 6

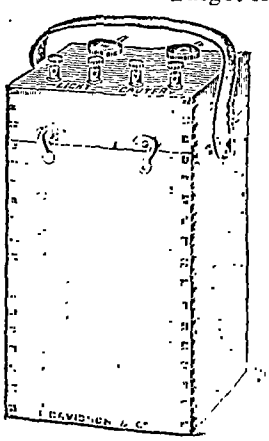
ELECTRIC PHARYNGOSCOPE.

New optical system giving much improved view.



The optical system as indicated above the lamp can be rotated as in a cystoscope so as to bring into view the *pharyngeal nares*, the *larynx*, *epiglottis*, the *vocal chords*, and the *Eustachian tubes*. A suitable catheter in position is easily observed.

Price ... £5 15s.; or in Walnut Box £6 5 0
"Davon" Dry Battery for above 0 7 6
Pharyngoscope with Battery and Rheostat, contained in Walnut Box 7 5 6

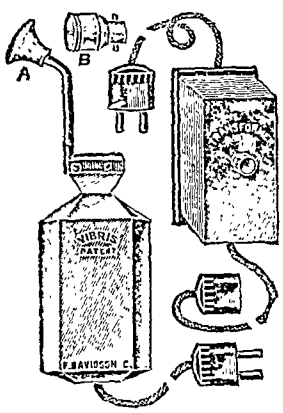


A NEW PORTABLE SET FOR CAUTERY AND LIGHT.

No. 18c. 0 to 4 Volts. Actual capacity 20 Amp. Hours.

It comprises a new pattern 4-volt glass accumulator made without plate separators. Concealed rheostats for cautery and light, actuated by rotating knobs on the lid, permit of very easy and gradual adjustment. Separate terminals for cautery and light allow of both being employed at the same time. The box is of walnut.

This constitutes an achievement in the production of a highly efficient apparatus at the very moderate cost of £4 5 0



A NEW INSTRUMENT FOR VIBRATORY PERCUSSIVE MASSAGE,

WORKING ON THE PRINCIPLE OF THE ELECTRO-MAGNET,

THE "VIBRIS" British Patent No. 289712

SUPERSEDES ENTIRELY EVERY OTHER FORM.

Special Features: There is no internal motor. It operates direct from the house current. It is absolutely safe in anyone's hands. The "VIBRIS" is only 6 inches long and weighs but 9 ounces. Results are obtained by:

(1) Deep Percussive Action for Internal Organs;
(2) Massage, Deep and Extensive, of the Muscle Masses of the Body;
(3) Superficial Massage (of the Scalp or Face).

PRICES:
Without Transformer
£2 10 0
for A.C.
With Transformer
£3 5 0
for D.C.
Please state voltage, etc.

Dr. ALQUIER, late chief of the Clinic Salpétrière, Paris, reports in the "Gazette des Hôpitaux": "Many instruments have been devised. After trial I have adopted that working on the principle of the Electro-Magnet, and the 'VIBRIS' is a REAL MEDICAL INSTRUMENT. The oscillations are double the number of the periods of the current, etc., etc."

Dr. R. P. writes: "What has been lacking until to-day was a practical instrument. The 'VIBRIS' with its frequent rhythmic vibrations fills the vacancy. I have used it with excellent results in the following cases (description curtailed):

1. Man, aged 56 years, presenting rheumatoid hydrarthrosis of both knees. From January to August, 1928. Compression, immobilization, local revulsion, radiotherapy, diathermy, opotherapy (thyroid in small doses), lithine were employed in succession. Result: very incomplete: effusion diminished without disappearing, pain persisted in the two knees with thickening of the synovial lining. In August, massage with the 'VIBRIS' at the rate of two sittings of 10 minutes daily was commenced. Result: Notable decrease of pain after the first day. At the end of a week no trace of articular swelling remained. Now the knees have resumed their normal shape, movements are perfectly free, and the patient declared himself cured.
2. Rheumatoid arthritis in a man of 60. After 10 days' pain disappeared, all movements without distress, and indeed with agility.
3. Two years pain, despite treatment, resulted in the painful deformities of chronic rheumatism. After 15 days' treatment with the 'VIBRIS' no more suffering, and the articular deformities were clearly reduced in size, movements of fingers quite free and painless."

FULL PARTICULARS OF ABOVE CASES IN BROCHURE M, POST FREE.

In Pernicious Anæmia

THE Liver Extract offered by Parke, Davis & Co., for use in the treatment of pernicious anæmia, is prepared by a method that has been shown to produce an exceedingly active product. It is supplied in vials each containing the extract from 100 grammes (nearly 4 ounces) of fresh liver, the contents of three or more vials being taken daily.

The P., D. & Co. Liver Extract is a palatable preparation with a pleasant salty taste, and it may be taken sprinkled over potatoes, meat, or bread. Its miscibility with water, milk, soup, orange or lemon juice, and other liquid foods also suggests other acceptable modes of administration.

Liver Extract

(Parke, Davis & Co.)

Supplied in packages of 24 vials.
Further details will be furnished on request.

PARKE, DAVIS & CO. BEAK STREET, LONDON, W.1

INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Helped by an endowment fund, an Intermediate Hospital of 25 beds (later to be increased to 50 beds) is now open for suitable general surgical cases at 17, Park Lane, London, W.1, in which the fees for a room cost only three guineas a week.

(The whole scheme is an attempt to help people unable to pay ordinary full surgical expenses, and yet at the same time to avoid any semblance of a charity which would be distasteful to such.)

All further particulars can be obtained from the Secretary or Matron at 17, Park Lane.
Telephones: Grosvenor 2312 & 2313.

A TYPICAL SCALE OF REDUCED FEES FOR SURGICAL CASES IN THE ANNEXE CLINIC OF THE HAROLD FINK MEMORIAL HOSPITAL AT 17, PARK LANE.

Hospital Fees, including Nursing, 3 guineas a week (limited to an average stay of 3 weeks)	£9 9 0
Dressings, Theatre Fees, etc.	1 1 0
Assistant Surgeon at operation (quarter usual charges)	2 2 0
Anæsthetic Fee (one-third usual charges)	3 3 0
Surgical Fees for Major Operation (from one-quarter usual charges, according to patient's means) ... ... (say)	26 5 0
(From Forty guineas inclusive fee)	£42 0 0

N.B.—The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant, who will take charge of the after-treatment while in hospital, and be paid direct by the patient his usual fees for such attendance in addition to the fee as Anæsthetist or Assistant at operation.

When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon-in-Chief (with a view, for example, to a Bismuth Meal, Cystoscopic or X-ray Examination, etc.), all that is necessary is to telephone either the Secretary or Matron, and an appointment will be made. (Proportionately reduced fees only charged therefor.)

Telephones: Grosvenor 2312 & 2313.

All rooms are of course separate, and hold one patient only, there being no wards.

ULTRA-VIOLET IRRADIATION—

THE value of irradiated milk for rachitic children, and in cases of tuberculosis of the bones, has been shown many times. (See *British Medical Journal*, March 28th, 1925; *The Lancet*, January 2nd and December 25th, 1926; *The British Journal of Radiology*, February, 1926; and *The Journal of Actinotherapy*, June, 1928). But hitherto the process of irradiation has always tainted the final product.

This difficulty has now been definitely overcome!

by

The 'SCHEIDT' PROCESS

in which COLD QUARTZ TUBES with remarkable U.V. spectra give an easily controlled and positive activation, and leave the products

UNCHANGED in TASTE or ODOUR

THE ONLY PROCESS OF EFFECTIVELY IRRADIATING MILK WITHOUT TAINT OF OZONE AND CARBON DIOXIDE.

THE 'Scheidt' Apparatus for cold tube activation is now installed, and in process of installation, at many of England's leading Clean Milk Farms and Dairies. These Farmers understand Milk and how it should taste where Infant Nurture is in question.

They have adopted the 'SCHEIDT' PROCESS!

Clinical, X-ray, and Blood Tests, carried out by eminent medical men using only the Scheidt Cold Tube apparatus (as against Quartz Lamp), are available, and have been quoted in the literature of Foreign Competitors, who appear to have thus paid an unconscious tribute to the value of the 'Scheidt' process.

MEMBERS OF THE MEDICAL PROFESSION ARE INVITED TO A DEMONSTRATION AT

LEWIS'S PUBLICATIONS

JUST PUBLISHED. EIGHTH EDITION. With 91 Illustrations in the Text and 2 Plates. Demy 8vo. 21s. net; postage 9d.

HYGIENE AND PUBLIC HEALTH

(PARKES AND KENWOOD).

Revised by HENRY R. KENWOOD, C.M.G., M.B., F.R.S.Edin., D.P.H.Lond., Emeritus Professor of Hygiene and Public Health in the University of London, etc.; and HAROLD KERR, O.B.E., M.A.Dunelm. M.D.Edin., D.P.H.Camb., Professor of Hygiene and Public Health in the University of Durham, etc.

Extract from Preface: We have carefully revised the last edition, and, by many deletions and additions, have brought the book up to date; and in the treatment of such an extensive subject we have kept prominently in view the practical needs of the student.

JUST PUBLISHED. With Illustrations. Demy 8vo. 12s. 6d. net: postage 9d.

ELEMENTARY MEDICINE IN TERMS OF PHYSIOLOGY

AN INTRODUCTION TO CLINICAL WORK.

By D. W. CARMALT JONES, M.A., M.D.Oxon., F.R.C.P.Lond., Professor of Systematic Medicine, University of Otago, New Zealand Physician, Dunedin Hospital, New Zealand; Consulting Physician, Westminster Hospital, etc.

NOW READY. With 186 Illustrations, included in 93 Plates (1 Coloured) and the Text. Demy 8vo. 25s. net.; postage 9d.

CHRONIC (NON-TUBERCULOUS) ARTHRITIS

PATHOLOGY AND PRINCIPLES OF MODERN TREATMENT.

By A. G. TIMBRELL FISHER, M.C., F.R.C.S.Eng., late Hunterian Professor, Royal College of Surgeons of England; Assistant Surgical Unit, University College Hospital; Author of "Internal Derangements of the Knee-joint," and "Treatment by Manipulation," etc

"Mr Timbrell Fisher has established the existence of facts hitherto unknown and has made valuable contributions to our knowledge."—BRIT. MED. JOURN.

JUST PUBLISHED. With 50 Illustrations Crown 8vo. 5s. net; postage 3d.

BRANCHIAL CYSTS

and other Essays on Surgical Subjects in the Fascio-Cervical Region.

Telegrams: PUBLICAVIT, EUSROAD, LONDON. Telephone: MUSEUM 7756 (3 lines).

THE BRITISH JOURNAL OF UROLOGY

Edited by

FRANK KIDD, M.Ch., F.R.C.S. H. P. WINSBURY WHITE, F.R.C.S.

FIRST NUMBER MARCH JUST PUBLISHED

Quarterly 6/- net. Annual Subscription 20/- (post free).

The first and the only English periodical devoted exclusively to the consideration and advancement of this ever-increasing and important branch of Medical and Surgical Science, and issued under the auspices of an Editorial Committee, the members of which are noted for their interest in urological work, both in the United Kingdom and in the British Dominions Overseas. The Committee confidently appeals to all who are interested, including the General Practitioner, whose interests have not been overlooked, to support the Journal by becoming regular Subscribers and sending their orders at once.

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph; Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 52 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"The book presents a comprehensive account of modern knowledge of cardiology."—BRITISH MEDICAL JOURNAL.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

THIRD EDITION. JUST PUBLISHED. Illustrated. 8vo. 42s. net.

DISEASES OF THE LIVER, GALL-BLADDER, AND BILE-DUCTS

By Sir HUMPHRY ROLLESTON, Bart., M.D., Regius Professor of Physic in the University of Cambridge; and JOHN WILLIAM McNEE, D.S.O., M.D., D.Sc., Associate Physician to University College Hospital.

British Medical Journal: "This new edition is a monument to the learning, diligence, and clinical experience of the writers, and a credit to British medicine. It is both exact and exhaustive. . . . As a standard work of reference the book deserves, and will no doubt enjoy, an even greater measure of success than it has had hitherto."

MACMILLAN & CO., LTD., LONDON, W.C.2.

"Should be in the possession of every medical man."—*Glasgow Medical Journal.*

URINARY SURGERY

A Handbook for the General Practitioner

By W. K. IRWIN, M.D., F.R.C.S.,

Assistant Surgeon, St. Paul's Hospital for Genito-Urinary Diseases.

¶ "Clearly written . . . furnishes the practitioner with information of great practical value in his everyday work."—*British Medical Journal.*

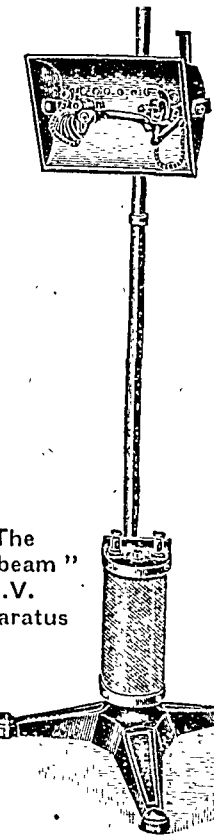
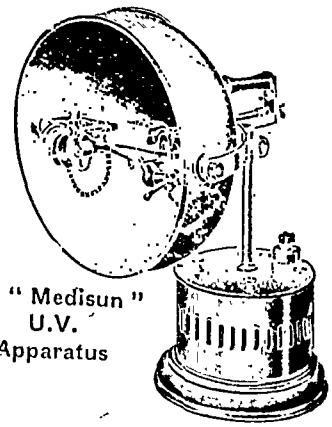
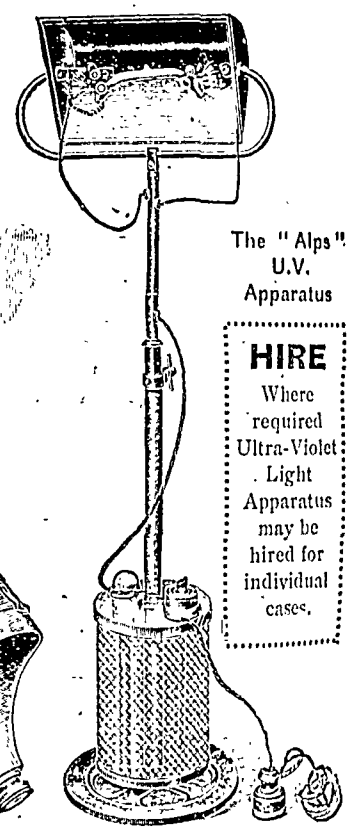
ULTRA VIOLET LIGHT



The "Sunbeam" U.V. Apparatus



The "Medisun" U.V. Apparatus



The "Alps" U.V. Apparatus

The models illustrated provide at economical cost a highly efficient source of Ultra-Violet Radiation. Widely approved by the Medical Profession on account of their simplicity and dependability, and 100% British.

THE "MEDISUN" U.V. APPARATUS

Quartz Mercury Vapour Type.

Designed for whole body or local applications. Suitable for general practitioners, or for use in the homes of private patients.

PRICE, for use on direct current - £12
PRICE, for use on alternating current - £18

"SUNBEAM" U.V. APPARATUS

Designed for Home Use, the Quartz Mercury Vapour Burner is less powerful than our other Models and consumes less current.

PRICE, for use on direct current - £15 10s.
PRICE, for use on alternating current £25

THE "ALPS" U.V. APPARATUS

Designed for Home or Professional use. Fitted with standard size Quartz Mercury Vapour Burner.

PRICE, for use on direct current - - - £25
PRICE, for use on alternating current - £41

THE DR. PERCY HALL U.V. APPARATUS

(Dual Purpose Model)

Provides in a single apparatus the means of applying Ultra-Violet Radiation either generally, locally, or internally by quartz applicators or specula. Acknowledged to be the most perfect type yet designed.

PRICE, for use on direct current - - - £38
PRICE, for use on alternating current - - £53

THE "TRINITY" U.V. APPARATUS

Designed to provide the radiation of Tungsten Arc, Carbon Arc, and Mercury Vapour Arc, so providing a selection of radiations at the will of the operator. Handsomely finished and made throughout in our own London Works.

PRICE, for use on direct current £41
PRICE, for use on alternating current £55

"VITA" GLASS OR ARTIFICIAL RADIATION!

Separate uses for each in the safeguarding of Public Health.

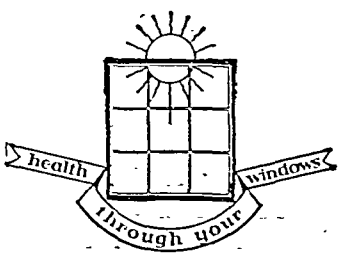
The uses of "Vita" Glass are distinct from the uses of artificial radiation and the employment of one does not mitigate against the use of the other.

While the ultra-violet lamp may be useful in the individual treatment of active disease, "Vita" Glass is best applied to the broader requirements of public health. By allowing free passage to natural ultra-violet light, "Vita" Glass acts as a permanent daily health measure and a gentle restorative in convalescence.

"Vita" Glass has been subjected to rigorous tests in smoky industrial areas and indisputable evidence is available in proof of its powers to transmit the ultra-violet rays. Over 150 hospitals and 100 schools are fitted with "Vita" Glass in this country alone.

"Vita" Glass is the only British window glass of its kind and its cost to-day is but moderate. Medical Officers of Health and others interested in "Vita" Glass are invited to write for fuller particulars to the "VITA" MARKETING BOARD, 9, Aldwych House, London, W.C. 2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.



"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

V.157

TOXINS
and
Arterio-Sclerosis

The great change that has been brought about in the treatment of arterio-sclerosis and certain other circulatory diseases through the widespread conviction that—as pointed out by Bishop*—

> "The vast majority of cases as they occur in adult life are due to the indirect influence of intestinal putrefaction upon the blood vessels and nervous tissue"

is of more than passing interest to the medical practitioner, now that we have a really efficient non-toxic intestinal bactericide that can be administered with the certainty that it will not only destroy the causal agents of the putrefaction referred to by Bishop, but will do so without absorption or toxic action.

N.Y. Medical Journal, September 9th, 1911.

The efficiency of Dimol in the treatment of *many other intestinal conditions of bacterial origin* is conclusively told in the interesting clinical reports, which, together with a brochure dealing with the pathological significance of the intestinal toxaemias, will be sent to any physician on application to the

Dimol Laboratories, Limited, 40, Ludgate Hill, London, E.C.4.

Therapeutic Ointments

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

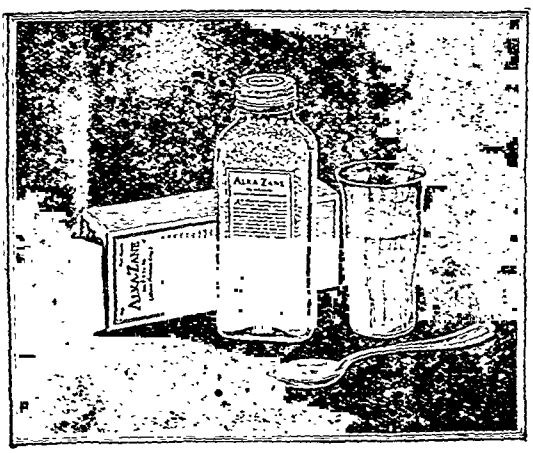
These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

ALKA-ZANE



A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

is a palatable and rational antacid, indicated in all conditions of relative hyperacidity, rheumatism, gout, intestinal, gastric, and certain cutaneous disorders.

Prompt in action, lasting in effect, it promotes diuresis, neutralizes excess acid production and helps to rebuild the alkaline bases.

The efficiency of Alka-Zane is demonstrable by the briefest of trials.

A supply for clinical use and literature sent gratis to physicians on request.

Francis Newbery & Sons, Ltd.,

Manufacturing Pharmacists Since 1856.

Disturbances of Menstruation & the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases. The chemical composition of Kalzana, calcium-sodium-lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had acute dysmenorrhoea; this is cured apparently."

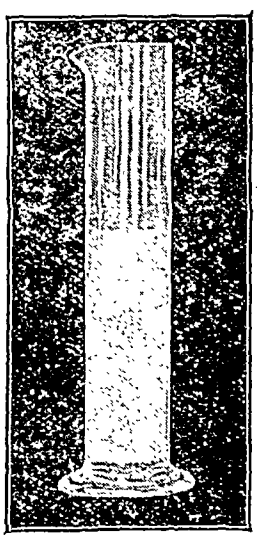
Kalzana is dispensed by Chemists in air-tight packets containing 50 and 100 tablets. Free from harmful by-effects and is pleasantly flavoured.

Kalzana

Made by A. WULFING & CO., Amsterdam, Holland.

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available at 15/- per 1,000 tablets Adequate samples for clinical trials, sent with pleasure, upon request.

THERAPEUTIC PRODUCTS LTD. (Dept B.M.J.32), 24/27, HIGH HOLBORN, LONDON, W.C.I.



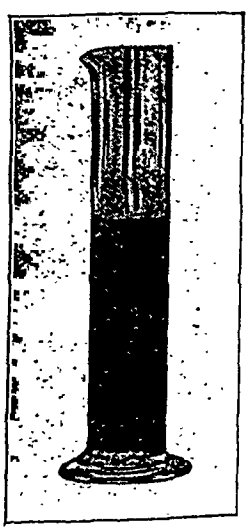
A Showing the heavy curd formed by the action of gastric juice on ordinary cow's milk.

The 'Allenburys' DIET

A Stimulating and Sustaining Food Beverage

A solution to the problem of feeding in many acute and chronic affections is found in the use of the 'Allenburys' Diet, which presents distinct advantages over cow's milk both with regard to food value and digestibility. The 'Allenburys' Diet is a palatable and highly nutritive food beverage prepared from pure fresh full-cream milk and whole wheat, and is particularly easy of assimilation. It replaces with advantage milk and the milk dishes commonly employed in sickness and convalescence and can often be taken and retained where other foods are rejected. As a stimulating and sustaining beverage for people of all ages, it is infinitely superior to tea, coffee, etc. It can be made in a minute simply by adding either boiling water or milk.

In tins at 2/1, 4/- and 7/6.



B Showing the finely flocculent curd formed by the action of gastric juice on the 'Allenburys' Diet.

Descriptive Literature and free clinical sample will be gladly sent on request.

ALLEN & HANBURYS LTD., Bethnal Green, London, E.2.

SHADOFORM

A preparation from which a liquid barium meal can be prepared at a moment's notice is of great value to the radiologist.

Shadoform is a soft powder with which a palatable meal of cream-like, non-gritty consistency is prepared merely by the addition of water; the meal is non-toxic, non-irritant, and retains its uniform opacity for a long period.

BARIUM SULPHATE B.D.H.

For the administration of a solid barium meal, efficacious yet free from toxic effects, Barium Sulphate B.D.H. is the ideal preparation.

T.I.P.

(Tetra-iodo-phenolphthalein B.D.H.)

The sodium salt of T.I.P. is made specially for use in cholecystography. It is guaranteed non-toxic, every batch being tested physiologically in the B.D.H. laboratories before issue.

Literature in reference to any of the above will be sent on request

THE BRITISH DRUG HOUSES LIMITED LONDON N-1

X/R (3)

OVALTINE

AN EFFICIENT GALACTAGOGUE.

In addition to its value as a means of promoting the nutritional welfare of the mother and child, clinical experience extending over many years has conclusively shown that "Ovaltine" has specific galactagogue properties. As a result of its administration, there almost invariably follows a marked improvement in the flow and quality of the milk.

The following is an example of many reports received:

> "In more than one case I have found 'Ovaltine' bring back the milk supply after everything else had been tried. In one case I discontinued the use of 'Ovaltine' after the desired result had been obtained, but I found at the same time the milk supply also diminished, necessitating the resumption of the use of 'Ovaltine.'"

To ensure adequacy of the milk supply many physicians order the use of "Ovaltine" to commence during the eighth month of gestation and to be continued throughout the nursing period. In this way the mother is not only enabled to withstand the extra strain which the childbirth throws upon the system, but to nurse her child from the outset in the best possible way. "Ovaltine" is delicious as well as highly nutritious, and involves no troublesome preparation.

A liberal supply for clinical trial sent free on request.

OVER 800 BRANCHES IN GREAT BRITAIN.

CONVENIENT AND CLEAN IN USE

MORE CERTAIN IN ITS ACTION THAN THE OLD-FASHIONED POULTICE

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

Composed of:

Ac. Boric., Methyl Salicyl., Ol. Menth. Pip., Thymol, Glycerine, and Kaolin.

Price 2/- per 1 lb. tin

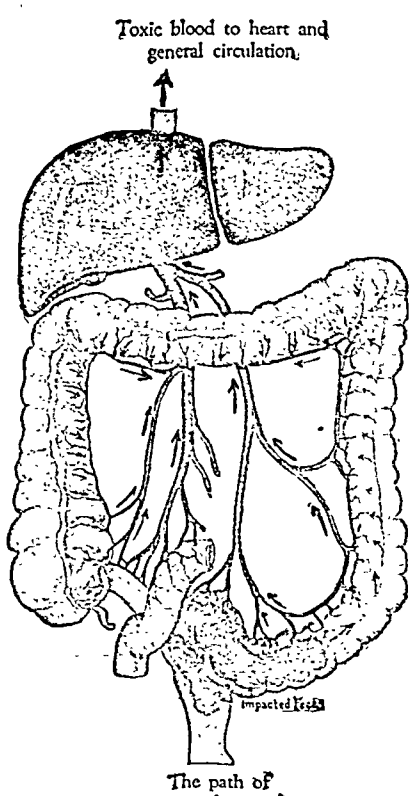
Dissolves Intestinal Toxins



The path of Intestinal toxemia

Not the least valuable of its properties is the behaviour of Nujol toward intestinal toxins.

If a watery solution of indol be shaken up with Nujol, more than half the indol is quickly taken up. Nujol readily dissolves this and other waste and poisonous substances, many of which are more soluble in Nujol than in water. Once absorbed in Nujol they cannot be absorbed by the system, as Nujol itself is non-absorbable.

The brownish colour of Nujol as seen in the stool is partly due to toxins which it holds in solution.

Nujol is a safe and effective treatment in all types of constipation and intestinal toxemia.

'PEPSENCIA'

Is radically different from the ordinary fluid "pepsin" preparations because it contains the entire soluble constituents, organic and inorganic, of the stomach glands, all the various complex potent catalytic constituents. It is not made by dissolving "pepsin" in a vehicle; it is an entire gastric juice extract.

To prescribe 'Pepsencia' is to give the patient the benefit of a standardised product of long maintained reputation and efficacy, of established value in medical practice as a digestant, a vehicle, an aid to other treatment; useful also in therapeutic feeding as a means of preparing the well-known milk foods junket and whey.

Supplied in four sizes: 4-oz., 8-oz., 16-oz., and W. Qts.

Originated and Manufactured by
Fairchild Bros. & Foster (Inc. N.Y.).

BRAND'S ESSENCE OF BEEF for INVALIDS

has enjoyed the confidence of the medical profession for over 90 years. A nourishing stimulant that demands the least amount of energy in the process of assimilation and increases the means of defence by raising the powers of resistance.

Mark it in your memo book

Brand's Essences are scientifically prepared, in jelly form, from the finest English meats, and contain upwards of eleven per cent. of proteid. The nourishing and stimulating properties are IMMEDIATELY ABSORBED, without residue, in the alimentary canal. No time is lost in process of assimilation. No work entailed by the digestive organs. Absolutely pure. Contains no gelatine, colouring, or preservatives. Good for young and old alike.

BRAND'S ESSENCE OF CHICKEN contains the same nourishing and stimulating properties as Brand's Essence of Beef, and for over 90 years has been recommended by the medical profession when required by prevailing conditions.

Sold by Chemists Everywhere

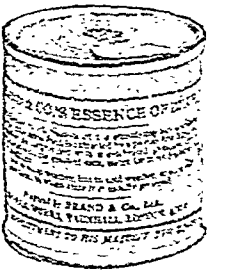
BRAND AND COMPANY LTD., LONDON, S.W.8.



B

The MEDICAL PROFESSION and HUMANISED TRUFOOD

THE success of Humanised Trufood is attributed to the fact that it is securing, in constantly increasing numbers each month, the support of doctors throughout the country.

Judged by the rate of progress over the last few years, we have every reason to anticipate that Humanised Trufood in the very near future will surpass the sales volume of any infant food in Great Britain.

Statistics alone do not make us arrive at this conclusion; it is due to the knowledge that there is not another baby food which so closely resembles breast milk, and to the fact that practitioners all over the country are recognizing the truth of this statement.

May we send you literature dealing with the relative merits of alternative milk foods?

DIPHTHERIA ANTITOXIN D.S.I. BRAND

(Concentrated and Refined)

As a result of prolonged investigations on the production of anti-diphtheritic serum an antitoxin, conforming to the following specifications, is now available to members of the medical profession.

Concentration of 2,500 units per c.c.
Protein content of less than 10%

The advantages of high concentration are obvious, especially in cases where large doses are indicated; whilst the low protein content reduces to a minimum the risk of serum sickness.

Diphtheria Antitoxin D.S.I. Brand (Concentrated and Refined) is prepared in such a manner that the maximum reaction velocity is maintained in spite of the great concentration. It is issued as follows:—

Super-concentrated and Refined—2,500 units per c.c.

Rubber-capped vials of 4 c.c. containing 10,000 units
" " 8 c.c. " 20,000 "

Concentrated and Refined—1,500 units per c.c.

Sealed ampoules of 1 c.c. containing 1,500 units
" 2 c.c. " 3,000 "
Rubber-capped vials containing 4,000 units
" " 8,000 "
" " 10,000 "

The concentrated and the super-concentrated are both guaranteed not to exceed 10% in protein content.

V.S. 12

Prescribe 'Mistol' for the Nose and Throat.

MISTOL has proven especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Mistol consists of menthol, eucalyptol, and camphor carefully combined in proportions recommended by leading nose and throat specialists. A specially prepared petroleum base keeps the soothing, healing ingredients in direct contact with the mucous membrane for a considerable length of time. Moreover, it prevents it being easily washed away by the natural secretions.

Mistol and the Mistol Dropper are a real advance in nose-and throat therapy. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. Unlike douches, Mistol avoids any possibility of sinus trouble. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Sold in original sealed cartons containing a—

Local Anæsthesia in Surgical Practice

CERVICAL ADENITIS.

Typical Case.

The following case will illustrate the application of Local Anæsthesia in children in whom the establishment of General Anæsthesia would seem especially hazardous.

B. D., aged 9 months.
Diagnosis: Suppurative cervical adenitis.
Operation: Incision and drainage.
Anæsthesia: Local infiltration, 20 c.c. of a 0.5 per cent. Novocain-Adrenaline solution.
Operation: A direct infiltration was made over the swelling, using 20 c.c. of a 0.5 of 1 per cent. Novocain-Adrenaline solution. The skin was picked up with towel pins to avoid pressure, and a transverse incision was made down to the cervical fascia. At this point the operation was delayed when the cervical fascia was infiltrated. This layer was then picked up with towel pins and a sharp-pointed hemostat was forced through and spread widely, opening the abscess.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance. The reason for this may be briefly stated:—

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state.

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use.

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion.

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc.) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds. The extent of digestion can be varied; *it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and is free from rough irritant particles.

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr. Benger's admirable preparation."

A Physician's sample will be sent post free to any member of the Medical Profession making application to the Proprietors:—

PUBLIC NOTICE

re

"RYVITA CRISPBREAD"

and

"THE RYVITA CRISPBREAD HABIT"

We acknowledge with much pleasure and grateful thanks the volume of congratulations on our successful introduction of "Ryvita Crispbread" to the British Isles.

When we gave to the British public this new and invaluable food—creating throughout our country the *Ryvita Crispbread habit*—we started what has now become almost a revolution in the bread-eating habit of the nation.

"Ryvita Crispbread" is the successful outcome of generations of experience directed to making just this one thing *right*.

That it is, and does, all that we claim for it is proved by the welcome it has received from Doctors, Dentists, and food experts, who not only prescribe it but have it as the daily bread in their own homes.

Because of its success, not only with the professions and the experts, but with the ordinary folk of these islands, there have arisen a number of "imitation Crispbreads." Some of these are not bad—*as imitations*—some are bad, some quite bad.

We make "Ryvita Crispbread" in Sweden because this type of bread is essentially and *characteristically* Swedish. The special ovens which we use are a mere item compared with the skill and long experience needed to make Ryvita *right*. It has taken generations of experience devoted exclusively to making just this type of bread to win the present perfection of "Ryvita Crispbread."

Although we make "Ryvita Crispbread" in Sweden, we who own and control the Ryvita Company are British. We buy British when it is best. But, like most other British people, we *will* have the best.

When we smoke a cigar it must be—Havana made in Cuba. After dinner, when we offer our friends a glass of port—it must be port from Portugal. When we have a little party, our champagne must be genuine from France. The suggestion that you should buy imitation Crispbreads merely because they are "British made" is as ludicrous as it would be to claim pre-eminence for British Cigars—British Port—or British Champagne.

Whilst the Ryvita Company is proud of its achievement in popularising the healthful *Ryvita Crispbread habit* in this country, it entirely dissociates itself from these hastily prepared substitutes.

The genuine original "Ryvita Crispbread"—crisp, scrunchy, and delicious . . . . the bread of life and health—helps to make indigestion, constipation, malnutrition, and obesity unknown.

"Ryvita Crispbread" is sold by all good grocers and stores at 1/6 per 40–50 slice (1 lb.) carton; ½ lb. carton, 10d.

"RYVITA CRISPBREAD MAKES YOU FIT—AND KEEPS YOU SLIM"

The Original & Standard Emulsion of Petroleum

Angier's Emulsion

is made with petroleum specially purified for internal use. It is the original petroleum emulsion—the result of many years of careful research and experiment.

In Gastro-Intestinal Disorders

of a catarrhal, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful. The minutely divided globules of petroleum reach the intestines unchanged, and mingle freely with intestinal contents. Fermentation is inhibited, irritation and inflammation of the intestinal mucosa rapidly reduced, and elimination of toxic material greatly facilitated. An improved state of the digestive functions and modifications of the various symptoms traceable to auto-intoxication are notable results.

During Convalescence

After fever, dysentery, operations, or after any serious illness; Angier's Emulsion will improve and strengthen the organs of digestion and assimilation and enable patients to derive the fullest benefit from any prescribed diet. The creation of appetite and the return of normal digestion is quickly brought about by its regular use.

Frail, Nervous Patients

respond actively to Angier's Emulsion. It is a tonic in effect and an aid to digestion. Being a perfect Emulsion, it is presented in a form pleasing to the taste and acceptable to the most fastidious. Its good effects are accomplished in a safe and natural manner without entailing any extra work upon the weak or overburdened system.

ANCIENT JAPANESE *KOTO*, OR LUTE, SIMILAR TO THAT WHICH SERVED FOR OBTAINING AUGURIES FOR THE EMPRESS JINGO IN CONNECTION WITH HER EMPIRE-BUILDING EXPEDITION AGAINST KOREA. HER CONQUEST GAVE A GREAT IMPETUS TO CIVILISATION IN JAPAN.—Internal development, together with the idea of Yamato empire within her borders, seems to have progressed steadily for several centuries before our era, but the first great awakening to a sense of nationality is ascribed to the time of the Empress Jingo, whose name signifies "divine merit or success." This sovereign, whose semi-legendary story is believed to contain a large germ of truth, decided to gain dominion over Korea, "Land of Treasure," "Land of Gold and Silver," as she described it to her ministers, to whom she addressed the following message when her plans were complete: "To make war and move troops is a matter of the greatest concern to a country. Peace and danger, success and failure, must depend upon it. If I now entrusted to you, my ministers, the duties of the expedition we are about to undertake, *the blame, in case of ill-success, would rest with you. This would be very grievous to me.* Therefore, although I am a woman, and a feeble woman, I will for a while borrow the outward appearance of a man and force myself to adopt manly counsels. . . . . If the enterprise succeeds, all of you, my ministers, will have the credit, while, if it is unsuccessful, I alone shall be to blame." She then set out commanding in person her fleet and army. The expedition, which appears to have lasted about three years, ended with the submission of Korea and establishment of a Japanese control, which endured for several centuries. An enormous impetus was given to civilisation in Japan through the importation of literature and the arts. Material benefits accrued also in the form of iron, implements, precious metals, silk and other fabrics.

DATE: Jingo's Invasion of Korea, A.D. c. 200–300.

An Address
ON
THE PLACE OF SURGERY IN THE TREATMENT OF PEPTIC ULCER.*

BY
D. P. D. WILKIE, M.CH., F.R.C.S.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF EDINBURGH.

THE choice of this subject for my lecture requires a little explanation, if not apology. The question of the advantages of medical over surgical treatment of peptic ulceration, and vice versa, has been debated almost *ad nauseam*. My object in this paper is not so much to uphold one line of treatment against another as to review the facts regarding the etiology of chronic ulceration so far as we know them, and to formulate rational lines along which the physician and surgeon, working hand in hand, may determine in which class of case, and when, medical measures should give place to surgery.

It is no new discovery in medicine that peptic ulceration will frequently yield to rest, frequent fluid feeds, and alkalis; nor, on the other hand, is it altogether surprising that extensive gastric resections are survived and followed by comparative comfort. What the patient with peptic ulceration wants to know is, what type of treatment will in his case restore him to health in a reasonable time with a probable chance of his remaining well under something approaching ordinary dietary and working conditions.

ETIOLOGY OF ULCERATION.

Few subjects have engaged the attention of so many experimental research workers as this. It has been shown that gastric ulceration may be produced by many factors, singly or combined. Blood infection may produce multiple acute ulcers, deranged or interrupted nerve supply may lead to ulceration, retrograde venous embolism may occasionally cause ulcer. Buchner has recently shown that by a combination of starvation and the injection of histamine into rats gastric ulceration occurs regularly. As in the human subject, it occurs not in the acid-secreting part of the organ, but in the part immediately adjacent to this. Rowlands, Underhill, and Mendel, and recently Magee, Anderson, and McCallum, have shown that ulceration may appear in the stomach as one of the manifestations of deficiency disease, and Rogoff and Stewart that it may follow adrenalectomy, an operation which, as Dale has shown, produces a condition of the blood not unlike that following injection of large doses of histamine.

It has always been difficult in the experimental animal to maintain ulceration and to get the typical deep punched-out chronic ulcer found in the human subject. Further, in this particular case it is difficult to produce experimentally conditions which are quite comparable to those in the human being. We are therefore thrown back to a large extent upon our clinical and pathological observations on the human subject. We reflect on the fact that the condition is met with in relatively healthy young adult males; that its symptoms are, to begin with, strictly periodic; that hyperacidity is present in the early stages; that painful spasm, as evidenced by the relief obtained by swallowing anything, is the rule. Further, we remark that dental infection is a frequent but by no means constant accompaniment, and that in many cases there is a history of acute or chronic appendicular trouble. We find that constipation, worry, overwork, loss of sleep, excessive smoking, and irregular meals, particularly if these are of the carried or snack-counter type, all seem to precipitate or aggravate the condition, which is more common among the highly strung and nervous than among the more phlegmatic members of the community. We note that, whilst multiple acute ulcers may be widespread, the chronic variety is found in certain strictly localized sites along the lesser curvature of the stomach, especially at the point where the body of the stomach abuts on the pyloric canal, and in the first part of the duodenum, approximately half an inch beyond the pylorus, and, in the latter case, usually multiple, one on the anterior and one on the posterior wall. We have good grounds for stating that the cause of gastric and duodenal ulcers must be one and the same, as they are so frequently found together. In my own series of duodenal ulcers a coincident gastric ulcer was present in 15 per cent., and of gastric ulcers a coincident duodenal ulcer was present in over 50 per cent. of cases. That a certain degree of gastritis accompanies and probably precedes ulceration is a fact of experience. *Post-mortem* room observations show that multiple scars of healed ulcers are not uncommon, and frequently alongside an active penetrating ulcer are found the scars of other more superficial and healed ulcers.

What is the initial and primary factor in determining the ulcer? I believe that it is a blood-borne infection which settles in the lymph follicles of the stomach and duodenum, some of which soften and erupt on the surface, the devitalized tissue undergoing digestion and leaving small follicular ulcers. The infection is streptococcal in type, and the primary source is usually the teeth or tonsils, and possibly, in some cases, the appendix. My reasons for this belief are as follows: In many cases we have recovered a streptococcus in pure culture from the base of an excised ulcer. In a number of cases we have found a coincident streptococcal infection of the gall-bladder and the appendix, and, whilst we have not been able to demonstrate experimentally the same selective affinity of the streptococcus for the stomach and duodenum that we have for the gall-bladder, we have sufficient evidence to point to the probability of this being the case.

There is admittedly a great tendency for acute ulcers in the stomach and duodenum to heal. Why is it that a certain number of such ulcers develop into the chronic peptic variety, and why are they found in such definite restricted areas of the stomach and duodenum? If we examine the common ulcer sites we find two characteristic features—first, the mucosa is relatively fixed, and secondly, the blood supply is relatively precarious. The greater curvature of the stomach, which contains few lymph follicles and the mucosa of which is lax and mobile in order to accommodate itself to the changing capacity of the organ, is practically immune from ulceration. The lesser curvature, on the other hand, is rich in follicles, is comparatively a fixed part, and is capable of little expansion: a defect in its lining remains open and is, moreover, in the direct traffic route of the entering food. The first part of the duodenum is, like the stomach, part of the foregut, has a smooth, unfolded mucous membrane rich in lymph follicles, and receives the acid chyme practically undiluted.

If these facts explain to some extent the *site* of chronic ulceration, what determines chronicity? Clinically we recognize two features in ulcer cases—hyperacidity and spasm. Further, we know that factors such as worry, excessive smoking, etc., which upset the nervous system, may, and frequently do, contribute to the onset of an "attack" of ulcer symptoms. From radiological studies we learn that in the duodenal ulcer cases rapid initial emptying of the stomach occurs, and during this period the patient is free from discomfort. A small residue is left in the stomach; this is hyperacid, pyloric spasm sets in, and the patient experiences the typical gnawing pain which he can relieve to some extent by swallowing fluid or food, which will cause pyloric relaxation. The majority of duodenal ulcers are small and shallow, and if given rest and shielded from the hyperacid gastric chyme, the tendency to healing is well marked. In the case of gastric ulcer acid appears to play a less important part, indeed hypo-acidity is present in many cases of chronic ulcer; hypermotility is also less pronounced and pyloric spasm comes on earlier after taking food. The drag on the irritated lesser curvature after taking food induces painful local spasm, which handicaps the blood supply and does not favour healing. The pain is notably relieved by the recumbent attitude, which obviates or lessens the drag.

It is a notable feature in the history of ulcer cases that a country holiday will almost always dispel an attack—that is to say, fresh air, sunlight, and a change of diet have an immediate beneficial influence. In reviewing the etiology of peptic ulcer we must therefore consider,

* Delivered to the Hyde Division of the British Medical Association on January 24th, 1929; illustrated by lantern slides.

I believe, three main factors: infection, nervous influences, and a possible dietary vitamin deficiency. In this connexion Mr. Garnett Wright has suggested that the success of the modern medical treatment of ulcer depends on the correction of vitamin deficiency by the giving of raw eggs, cream, etc., to patients who were accustomed to live on tea, white bread, cakes, and tinned or cooked foods.

In the light of the facts stated above we can understand how the removal of septic foci in the mouth, rest in the recumbent position, the ensuring of adequate sleep, the cutting down or out of tobacco, the giving of small meals of fresh vitamin-rich fluid food at frequent intervals, and the supply of alkali, may together favour, indeed almost ensure, the healing of gastro-duodenal ulceration in all but old-standing and neglected cases.

THE RATIONALE OF SURGICAL TREATMENT.

Apart from emergency operations for perforated ulcer, operative treatment for peptic ulcer is a practice of not many years' duration. It may be said to have started when it was found what great relief followed a gastro-enterostomy for irremovable cancer of the pylorus. The earlier operations were all done to relieve a mechanical difficulty—that is, a stenosis resulting from the cicatrization of an ulcer in the duodenum or stomach. The brilliant results of such operations induced surgeons to try the same short-circuiting operation in cases of ulcer without stenosis in order to give rest to the ulcerated part. It was further found that the short-circuit permitted the entry of a certain amount of bile, mixed with pancreatic and duodenal secretion, into the stomach, and thus reduced acidity. This, the so-called physiological action of the stoma, was held by many, notably Paterson, to be the most beneficent effect of the operation. The results of gastro-enterostomy for chronic duodenal ulcer with some degree of mechanical difficulty from stenosis—that is, with a somewhat dilated stomach—were almost uniformly good. In a few regurgitant vomiting from a badly placed stoma resulted, and in a small percentage (less than 3 per cent.) a peptic ulcer developed at the stoma.

In another group, however, in which an irritable ulcer without stenosis but with marked hyperacidity and pronounced gastric hypermotility was present, the results of the short-circuiting operation were by no means so favourable. Here the danger of jejunal ulcer is a very real one, and only the most careful and prolonged after-treatment will prevent it. The consequence has been that an injudicious selection of cases for the operation, resulting in the development of jejunal ulceration in an unpleasantly large group of individuals, has prejudiced the good name of one of the most beneficent of surgical procedures.

The case of gastric ulcer is altogether different. After a few years of trial gastro-enterostomy was found to be most uncertain in its results in the treatment of gastric ulcer. Almost 50 per cent. of patients continued to have symptoms, and in a few cases malignant disease supervened on the simple ulcer which had not healed. As with duodenal ulcer, so with the smaller non-penetrating gastric ulcers, healing will result in a large proportion of cases under systematic medical treatment. When the ulcer is large and penetrating, however, even prolonged medical treatment will fail in many instances to cure, and during this long and tedious course of treatment malignant disease may have supervened and spread to the regional lymph glands or beyond them. The rule of the Mayo Clinic, that all penetrating gastric ulcers of 1 cm. or more in diameter must be regarded as potentially malignant and should be removed, is one that I would have our ultra-conservative and optimistic medical friends take to heart.

Size, penetration, and tendency to stenosis and hour-glass constriction should, in my opinion, be the indications for surgical intervention.

THE BLEEDING ULCER.

After a patient has had one or more severe haemorrhages the question of surgical intervention usually arises. The problem presents itself first as to the risk run by persevering with purely medical measures, and, secondly, as to the immediate risk of operation and the possibility of dealing with the bleeding ulcer in such a way as to give a reasonable hope of lasting cure. To maintain that a patient never dies of haemorrhage from an ulcer is to go contrary to facts. Any pathologist of experience can cite very many cases where haemorrhage from an ulcer was the immediate cause of death. The operation for haemorrhage during the acute and threatening stage is, however, not only a dangerous, but in my experience an unsatisfactory, one. More often than not the haemorrhage has stopped at the time of operation, no definite bleeding point can be dealt with, and the patient, even if transfused, is not in a fit condition to allow of the radical treatment which would appear to be the only rational means of ensuring against recurrence. I believe it is wiser to tide the patient over the immediate effects of the haemorrhage, taking the risk of another, possibly fatal, bleeding, and to operate not earlier than ten days after the last severe bleeding. If no radiographic examination has been made prior to the bleeding it is usually wiser to wait until this can be done, for if it shows no gross deformity, either in stomach or duodenum, it is questionable if any operation should be performed.

For the bleeding duodenal ulcer a short-circuiting operation may be successful, but in my experience it fails in about 40 per cent. of cases to prevent recurrence of bleeding sooner or later. The persistently bleeding duodenal ulcer is usually on the posterior wall, is penetrating, and shows little tendency to heal after a short-circuiting operation. It is in this class of case that a partial duodenectomy is, to my mind, indicated, and I would reserve this operation for this type of ulcer. If the patient's general condition or the technical difficulties make such radical treatment undesirable a temporary closure of the pylorus and a gastro-enterostomy may be carried out.

For the bleeding gastric ulcer local excision with a short-circuit or a partial gastrectomy is required. In both cases the suitable operation is no minor one, and should not be attempted until the patient's condition is such as to make the immediate risk little if at all greater than that of any major gastric operation.

CONSERVATIVE MEDICINE VERSUS RADICAL SURGERY.

In this country at the present time there is unquestionably a strong trend in favour of prolonged medical treatment of peptic ulcers, no matter at what stage or of what size the ulcers may be. The writings of MacLean and Hurst have done much to stimulate a renewed interest and zeal in the purely medical lines of treatment. This swing of the pendulum was perhaps inevitable after a period in which operative treatment was resorted to without much nicety of discrimination and selection of cases, with its inevitable aftermath of unsatisfactory results. On the Continent, on the other hand, the tendency has been in the direction of ever more radical surgery. It has gone so far that in some clinics a total extirpation of the "ulcer-bearing area" is the standard treatment for duodenal as well as for gastric ulcer. Some surgeons, with a naive disregard for the facts of physiology, remove what they term the acid-secreting part of the stomach with the object of avoiding a jejunal ulcer. As Buchner has so clearly pointed out, ulcers are found not in the acid-secreting parts, but in those which, whilst not secreting acid, are exposed to acid content.

THE ARGUMENT.

If we examine the basis of the argument of the ultra-conservative *school against operative* treatment we find that it rests on their experience with the surgical derelict—the few with regurgitant vomiting, and the rather larger number with jejunal ulcer. Also we find that they have a very natural aversion to the sacrifice of a large part of a most useful and highly specialized organ because of the presence on its wall of a small infective ulcer. Further, they state that, given time and care, even the largest gastric ulcers will heal under medical treatment.

On the other side their more surgically minded brethren point to the large number of the populace who suffer from chronic ulcer and who cannot or will not carry out the prolonged medical treatment and still more prolonged dietetic regime which some physicians advocate so strongly

Further, they emphasize the real danger of overlooking early malignant disease if chronic penetrating gastric ulcers are to be subjected for an indefinite period to persistent and unrelenting medical measures.

THE VIA MEDIA.

In this, as in so many fields in which strong and opposing views prevail, the truth will probably be found somewhere between the extremes. I suggest the following as the rational lines to follow in dealing with ulcer cases.

A. For all acute ulcers, for those which have not caused more than six recurrent attacks of symptoms, for those which give rise to no gross deformity in the radiogram and show no signs of true penetration, for those which have not given rise to more than one serious haemorrhage, and for those in highly nervous subjects, medical treatment should be given a fair and prolonged trial.

B. For all chronic ulcers causing gross deformity and organic stenosis, for all cases where more than six attacks have occurred, where strict dietetic regime is impossible, where there is definite *x*-ray evidence of serious organic deformity, for all the penetrating gastric ulcers, and particularly for those in which the *x*-ray photograph discloses a crater judged to be 1 cm. or more in diameter, surgery is demanded and medical treatment unjustifiable. For all ulcers which have bled freely on three or more occasions surgery must be considered.

THE CONSERVATIVE SURGERY OF ULCER.

How may we give the unquestionable benefits of surgery to the groups of cases indicated above, and at the same time avoid the unpleasant, and indeed dangerous, complications of regurgitant vomiting and jejunal ulcer, whilst conserving as much normal tissue as we can? For the duodenal ulcer with marked stenosis a posterior gastro-enterostomy, placed not too far to the left and with a roomy aperture in the mesocolon, cannot be improved on; the results are consistently good.

Perhaps the most impressive review of the results of the conservative surgery of duodenal ulcer is that given by Balfour, who followed up the cases of one *hundred medical men* operated on in the Mayo Clinic for duodenal ulcer. The average time since operation was eight and a half years. A gastro-enterostomy had been done in 82 per cent. of the cases, excision in 6 per cent., and gastro-duodenostomy in 2 per cent. In 90 per cent. the result of the operation was complete relief from symptoms, and in the great majority the reports were almost extravagant in their praise of the effects of the operation.

For the persistently recurring duodenal ulcer without much stenosis or gastric dilatation—the type which we feel should be cured by medical measures, as it often is for a short time—in the man who cannot take any liberties without suffering and will not lead "the life of a weaned child," for this type a gastro-enterostomy always carries with it a potential jejunal ulcer, and a gastro-duodenostomy is undoubtedly the operation of choice.

GASTRO-DUODENOSTOMY FOR DUODENAL ULCER.

In the last few years I have gradually substituted this operation for posterior gastro-enterostomy in all cases without very definite stenosis. At first I practised it mainly in female patients with a lax, readily mobilized duodenum, but latterly I have found that it can be done almost as easily and with equal advantage in the male. The rationale of the operation is that it excludes from the food stream the ulcer-bearing area of the duodenum; that the new opening is in the pyloric end of the stomach, the peristalsis of which is not interfered with; that the acid gastric contents are discharged into the second part of the duodenum directly opposite the point of entry of the bile and pancreatic juice; that the rest of the small intestines need not be disturbed, and incidental complications from adhesions, etc., are thus minimized; that the ulcer or ulcers are left untouched, a direct attack upon the average duodenal ulcer being, in my opinion, quite unnecessary.

The essentials for the operation are complete and effective mobilization of the second and the commencement of the third parts of the duodenum. To obtain this the *hepatic flexure of the colon must be freed, the peritoneum* on the outer side of the second part of the duodenum incised, the fascial bands, which hold down the second and especially the third parts of the duodenum, divided, and the duodenum brought to the surface. Morison's pouch is then packed off, and the anastomosis carried out with two layers of No. 00 catgut sutures. It is better to do the operation without clamps, as the less the duodenum is traumatized the better. In this operation the pylorus and first part of the duodenum are folded the one on the other, making an effective barrier to the passage of food through the pylorus. In the few cases where satisfactory mobilization of the duodenum has been impossible a Finney's operation has been performed with almost equally good results.

It may be urged against this operation that the post-operative course is frequently not so smooth as that of a posterior gastro-enterostomy. Against this, however, may be claimed the infinitely smaller risk of a peptic stomal ulcer. I have not encountered any, and I have only heard of two. The operation disturbs the normal physiology less than does a gastro-jejunostomy, and the possibilities of late complications are infinitely less. When the stomach is grossly dilated or markedly ptosed it does not give the effective drainage obtained by a gastro-jejunostomy, and in one case where drainage was unsatisfactory I had subsequently to perform the latter operation, which gave complete relief.

SURGICAL TREATMENT OF GASTRIC ULCER.

When an ulcer has actually penetrated the muscular coats of the stomach and is adherent to the pancreas, and especially when it is associated with one or more duodenal ulcers—which it is in over 50 per cent. of cases in my series—the chances of sound healing and lasting cure by medical measures are exceedingly small. Without in any way wishing to labour the question of malignant degeneration of simple gastric ulcer, and while considering that it is a relatively rare complication, I believe that it occurs sufficiently often to make long-continued medical treatment unjustifiable. It is well-nigh impossible to obtain reliable *figures on the question*. Two cases, however, where the course from simple ulceration to malignancy was observed, impressed me with the danger. In one case a man over 50 years of age had been under medical treatment for over eight years for what was *diagnosed as duodenal ulcer*. He came to operation on account of jaundice associated with a palpable swelling below the right costal margin—taken to be the gall-bladder. I found a healed duodenal ulcer and a large gastric ulcer, not palpably malignant, but associated with a large secondary malignant nodule in the liver. The edges of the ulcer were found to be infiltrated by malignant disease.

The second case was in a woman of 28 who, two years previously, had had a gastro-enterostomy performed for what appeared to be a simple peptic ulcer of the lesser curvature. When I saw her, two years after her operation, she had a palpable mass in the epigastrium. This proved to be a malignant mass on the lesser curvature spreading from the edges of a penetrating ulcer.

I believe that large gastric ulcers should be excised. Whether the operation be a partial gastrectomy or a free local excision with a gastro-enterostomy, a gastro-duodenostomy or a Finney's operation is, I think, a minor technical matter. Personally I prefer to do a local excision with a gastro-duodenostomy. This ensures free drainage from the stomach, and excludes the duodenal ulcer which is so often present as well, whilst conserving normal tissue and maintaining an attitude of respect for what, after all, cannot but be a useful organ.

The Cautery Method.—When an ulcer is found high on the lesser curvature and of no great size, the destruction of the base and floor of the ulcer by means of the thermo-cautery along with a short-circuiting operation, as introduced by Balfour, is a method which in my hands has given very good results. For larger ulcers—that is, for those in which surgical treatment is most clearly indicated—excision is, I believe, undoubtedly preferable.

Cholecysto-gastrostomy.—The bilification of the stomach by anastomosing the gall-bladder to that organ, advocated and practised in this country by Braithwaite, is based on

the conception that the neutralization of the acid gastric juice by the regurgitant fluid through a gastro-entero-stomy is due mainly, if not entirely, to the bile contained in that fluid. Whilst good results have been reported in cases of gastric ulcer so highly situated in the lesser curvature as to preclude excision, and in a number of cases of doubtful pathology with hyperacidity as their dominant symptom, the basis of the method is insecure, as bile in itself is not alkaline, and after a gastro-intestinal anastomosis it is the duodenal and pancreatic secretions rather than the bile which give the regurgitant fluid its neutralizing properties. I have carried out this operation in only two ulcer cases, one of very high lesser curvature ulcer and one of gastro-jejunal ulcer. In both cases some immediate improvement resulted, but the symptoms of acidity and pain returned.

Ulcer as One of Many Septic Foci.

No treatment of ulcer can bear the promise of lasting cure if it does not take cognizance of the other foci of infection which accompany it. The prevalence of dental infection is to my mind the most important single factor in determining the frequency of peptic ulcer. It is indeed surprising to find in the vast majority of the patients sent for surgical operation after ineffective medical treatment that gross dental infection has been left untreated. In many of these cases we recover from the pyorrhoeal pockets the same streptococcus as we find in the ulcer. Efficient dental treatment must, therefore, be a first consideration, no matter what other lines of therapy we may follow.

It is within the abdomen, however, that we so frequently find other infective foci which must be dealt with at the same time as the ulcer. The combination of an ulcer in the stomach or duodenum or both with infection in the gall-bladder and appendix is quite common. All these lesions must be dealt with if complete and lasting relief is to be obtained. The following brief note of a case will illustrate the significance of a thorough eradication of foci.

Mr. A. B., aged 57, had thirteen years previously had a gastro-enterostomy performed for duodenal ulcer. He obtained some temporary relief, but his old pain soon returned; he suffered from nausea, flatulence, and constant abdominal discomfort, and led the life of a chronic dyspeptic. On examination we found him emaciated, with a dilated stomach and tenderness over three points in the abdomen—just to the left of the umbilicus, just below the right costal margin, and in the right iliac fossa. *X*-ray examination showed his stomach to be dilated, the stoma stenosed and irregular, evidently from a jejunal ulcer. At operation a jejunal ulcer was found and excised and his stoma enlarged. His gall-bladder was thickened and inflamed, as was his appendix; both were removed. Regional lymph glands were taken from all three sites and from all the *Streptococcus viridans* was grown in pure culture. On injection into rabbits both cholecystitis and duodenal ulcer were produced. Since the second operation the patient has enjoyed perfect health and lost all his dyspeptic symptoms.

It may be that we shall eventually succeed by suitable inoculation in immunizing patients against these multiple streptococcal abdominal lesions, or, still better, by timely dental treatment and better dietary and hygienic treatment, in preventing them. Till then, however, surgery must continue to play a part in dealing with the full-blown lesions, and surgery, whilst conserving healthy tissue, must deal thoroughly and radically with the different foci.

An Address
ON
RADIUM AND ITS SURGICAL APPLICATIONS.

GIVEN BEFORE THE BRISTOL MEDICO-CHIRURGICAL SOCIETY
BY
H. S. SOUTTAR, M.D., M.Ch., F.R.C.S.,
SURGEON, LONDON HOSPITAL.

RADIUM was discovered by Madame Curie in 1898, and its discovery marks an epoch in the history of science. It destroyed at one blow the conception of the atom as an indestructible unit, upon which the whole of chemistry and the greater part of physics had been built, and it opened up a field of investigation which has provided work for physicists for the last thirty years, and has led to discoveries which have revolutionized all our ideas of the physical universe.

Soon after the element had been isolated Becquerel, by inadvertently carrying radium in his pocket, discovered its destructive action on the human tissues, but although attempts were made to turn this to surgical advantage, it was only in isolated cases and in special regions that effective results were obtained. Whilst fully recognizing the value of the work done with radium in diseases of the skin and in carcinoma of the cervix, one must admit that only lately have the surgical possibilities of radium been appreciated, or any attempt been made to exploit its powers. Indeed, those who have had the opportunity of studying the subject must feel that we are only at the beginning of what may prove to be a new epoch in the treatment of malignant disease. For the first time in the history of medical science we hold in our hands a power which beyond any question can cure cancer in many of its forms, and which can destroy a malignant growth without its surgical removal, and it is our business to explore its possibilities to their utmost limits.

This is a subject which none of us can afford to neglect, and it is essential that every surgeon should realize what can be done with radium and understand the methods by which it is applied. To use it effectively he must know something of the physical properties of the new weapon which has been placed in his hands, and I therefore make no apology in describing briefly those physical properties which are fundamental in the action of radium when it is used by the surgeon.

The revolutionary conception involved in the discovery of radium was the idea that an element could decay, and in the process of decay be transformed into an entirely different substance. It has been established, however, beyond any possible question that certain elements possess this power, and they can indeed be arranged in a number of definite series in which each element is the product of the last. The most important of these is the uranium series in which radium occurs, and you will see the parentage and descendants of radium set out in the family tree shown in Table I. Not only do we know its family history, but we know the expectation of life of each of its members, as represented by its half-value period, the time in which one-half of the element has disappeared, and you will see that this varies considerably, since while uranium attains the patriarchal age of five thousand million years radium itself is half gone in 1,750 years, and radium A in three minutes. It is indeed to this rapid decay of radium and the other elements in the centre of the table that we owe the surgical possibilities of radium. There is something which stirs me profoundly in this dry table. Th

TABLE I.—*The Uranium Series.*

Element.	Atomic Weight.	Radiation.	Half-value Period.
Uranium 1	238	$\alpha\,\beta\beta$	5,000,000,000 years.
Uranium 2	234	α	2,000,000 years.
Ionium	230	α	140,000 years.
Radium	226	$\alpha\,(\beta)$	1,750 years.
Radon	222	α	3.85 days.
Radium A	218	α	3 minutes.
Radium B	214	$\beta\,(\gamma)$	26.7 minutes.
Radium C	214	$\alpha\,\beta\,\gamma$	19.5 minutes.
Radium D	210	β	17 years.
Radium E	210	β	5 days.
Polonium	210	α	136 days.
Lead	206	—	—

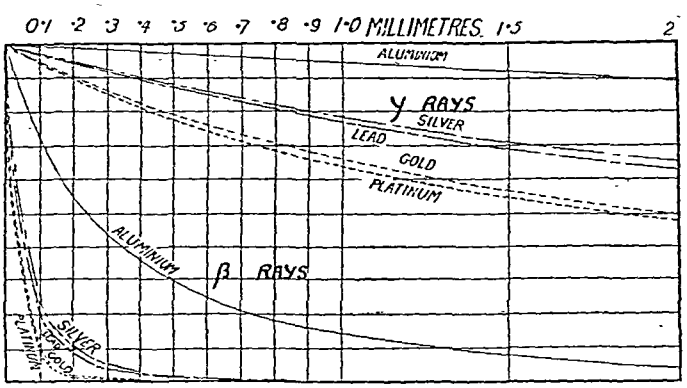
evolution of uranium occupies a period of five thousand million years, and it began perhaps when our world was a glowing nebula. For a few days only it exists as radon; for those few days perhaps—we are not yet quite certain—it offers to us the cure of cancer.

We have spoken of "decay," but in order to understand the real meaning of the term and its importance for our subject we must first say something of the modern view of the structure of the atom. We owe to Rutherford the conception of the atom as a minute solar system, in which the nucleus is the sun, whilst the electrons flying round it with inconceivable velocity are the planets. In very general terms radio-activity and mass are properties of the nucleus, whilst chemical affinities and spectroscopic properties are manifestations of the flying electrons. The electrons are all identical, each carrying the same negative charge: the nuclei are all different, but they are built up of the same units, electrons carrying a negative charge, and protons which each carry an exactly equal positive charge.

The simplest atom of all is the hydrogen atom, consisting of a single proton as nucleus, with a single electron flying round it. Next in order comes the helium atom, its nucleus built up of four protons and two electrons welded together, whilst its planetary system consists of two electrons whirling round the nucleus. To us its importance can scarcely be exaggerated, for the nucleus is identical with the alpha particle, so that an alpha particle may be regarded as a helium atom deprived of its two planetary electrons, whilst it does not require much imagination to see that it must carry a positive charge exactly double the negative charge carried by each electron. When we point out that the electron, set free to fly through space, is the beta particle, and that with its liberation is bound up the production of gamma rays, it will be realized that the helium atom carries in miniature the whole physical basis of our subject.

TABLE II.—*Dimensions of Waves and Atoms.*

Angström Unit (A.U.)	1/10,000,000 millimetre.
Wave length of green light	5,000 A.U.
,, of *x* rays	12 A.U. to 0.5 A.U.
,, of gamma rays	1 A.U. to 0.04 A.U.
Diameter of hydrogen atom	1 A.U.
,, of nucleus	1/25,000 A.U.
,, electron (β particle)	1/125,000 A.U.



Transparency of metals to beta and gamma rays.

Contrasted with these simple structures the radium atom presents an enormous complexity. Its nucleus is a dense cluster of 226 protons and 138 electrons, some at least of which are grouped together to form alpha particles, whilst around this nucleus whirl no fewer than 88 electrons. The formation is unstable and alpha particles are being constantly discharged from the nucleus, beta particles from the nucleus and from the planetary system. As each particle is projected into space the characters of the atom are changed. It is no longer radium, but one of its derivatives, and this is the physical interpretation of "decay." Radium becomes radon, radon becomes radium "A," which is so unstable that within a few minutes it has lost an alpha particle and become radium "B." Finally stability is reached in an atom indistinguishable from that of lead, and so far as we know no further change occurs.

If nothing further were said a very false impression might be gained of atomic structure, for I have said nothing at all about the size of the atom as a whole, or the relative sizes of its parts. The atom is so minute that to form any real impression of its size we must take an entirely new unit for our measurements: the most convenient is the Angström unit, one hundred millionth of a centimetre, often denoted by the symbol A.U. On this scale the wave-length of green light, in the middle of the visible spectrum, is 5,000 A.U.: the wave-length of *x* rays ranges between 12 A.U. for the soft rays and 0.5 A.U. for the hard rays; and the wave-length of the softest gamma rays is 1 A.U., whilst the hard gamma rays may be as short as 0.04 A.U.

On this scale the diameter of the hydrogen atom is almost exactly 1 A.U., but this is the diameter of the orbit of the electron as it whirls through space around the nucleus. The diameters of the nucleus and electron are far smaller, each being about 1/25,000 A.U. You may, indeed, represent the hydrogen atom by one golf ball travelling around another in an orbit about a mile across. On the same scale the diameter of a single tissue cell would be about 100,000 miles. When we talk about the impact of beta particles on the tissues it is well to bear these facts in mind. Even the most enthusiastic golfer will see something remarkable in the destruction, by quite a large number of golf balls, of an object relatively fifty times the diameter of the moon. And when, as will appear later, he sees that the destruction may equally well be produced not by the golf balls themselves but by the ether waves—gamma rays—which accompany their discharge, he will probably require the next letter of the Greek alphabet to express his feelings.

We are now at last in a position to understand the property of radium which gives to it for us its peculiar value, the radiation which accompanies decay. As we have seen, it takes three forms, the alpha, beta, and gamma rays, and we may now sum up briefly the very different characteristics of these three forms.

The alpha rays consist of particles identical with the nucleus of helium, each carrying a positive charge of electricity, and they are projected from the nucleus with a velocity of 10,000 miles a second. In spite of this terrific velocity they have little power of penetration and are stopped by a thin sheet of paper. Even in air they rarely travel further than a couple of inches, so that although they carry the great bulk of the energy produced by the dissolution of radium they are of no practical value in surgery.

The beta rays are formed by electrons, of very small mass, carrying a unit negative charge of electricity, and projected with any velocity up to 180,000 miles a second, falling just short of the velocity of light. The soft rays of low velocity are easily stopped by a thin sheet of aluminium, but the hard rays of high velocity can pass through 0.2 mm. of silver. All but a small percentage of beta rays are, however, stopped by 0.5 mm. of platinum or by a centimetre of the body tissues. Their surgical action is therefore very local, and it is often better to avoid it altogether by the use of screens.

The gamma rays are ether waves of exceedingly short wave-length, less than 1/5,000 of that of light. They are set up apparently by the discharge of the beta particles, they travel with the velocity of light, and their power of penetration is so great that they are scarcely affected by the screens which almost abolish beta rays; they can pass through several inches of lead, and they are only reduced by about 50 per cent. in passing through four inches of the body tissues.

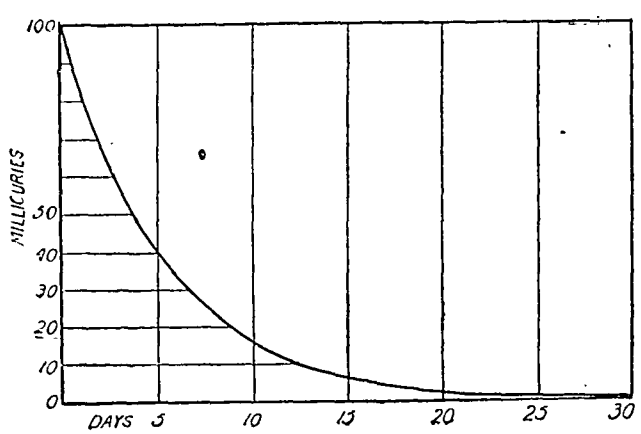
It is thus upon the beta and the gamma rays that the surgical action of radium depends. The former are destructive in their effect, and they are chiefly used in surface applicators for the production of superficial scarring. The gamma rays, on the other hand, have two very remarkable effects: they stimulate the activity of the tissue cells, and especially the production of fibroblasts, and they have a definite selective action on tumour cells, probably, at the moment of their division, causing them to disintegrate and disappear. Their total effect when they can be suitably applied is to cause the disappearance of a malignant tumour and its replacement by a scar.

I must say one word more about the process of decay. The decay of radium is so slow that where we use the element itself we may regard it as a constant source of radiation. It produces radon at a constant rate, and this by its decay produces its still less stable products with mathematical uniformity. In many instances, however, it is more convenient to use radon rather than the element itself, and the whole situation is then entirely changed. Let us consider for a moment the properties of this extraordinary substance, still more remarkable than the radium from which it springs.

Radon, the emanation of radium, is the very spirit through which it exercises its powers. It is a heavy inert gas with no known chemical affinities, and it decays with such rapidity that in 3.85 days one-half of it has vanished, whilst at the end of nine days only a fifth remains. So long as it remains in contact with radium the decay is made up by production, so that after a certain time equilibrium is established. If radium is left undisturbed this is reached in about a month, and thereafter production and decay exactly balance. At this stage radium has reached its maximum radio-active power, and the radio-active power of a milligram of element is defined as a millicurie.

TABLE III.—*Decay of Radium Emanation.*

Days.	Millicuries.	Days.	Millicuries.
0	100	12	11.5
1	83.5	14	8.0
2	69.8	16	5.6
3	58.3	18	3.9
4	48.7	20	2.7
5	40.7	22	1.9
6	34.0	24	1.3
7	28.4	26	0.93
8	23.7	28	0.65
9	19.8	30	0.45
10	16.5		



And now we meet with the most extraordinary fact of all. This gas radon can be separated from the parent radium and packed in containers, carrying with it what, for all practical purposes, is the entire radio-active power of the radium, which is left behind for the time being entirely inert. The total volume of the gas is only a minute fraction of that of the radium from which it arose, and if you purchase one gram of radium at a cost of £12,000, wait patiently for a month, and then with the most delicate precautions pump off the emanation, you will be rewarded with 0.6 of a cubic *millimetre* of evanescent gas. But that minute bubble might cure fifty cases of cancer before it itself expires.

You will see at once the extraordinary convenience of using the emanation instead of the element. It carries all the powers of its parent for a few days, and then the... simply vanish; its bulk is infinitesimal; its monetary valu... is *nil*. It can be inserted into a growth and simply le... to decay, and the patient can be sent home without ris... to himself or to the radium capital of the hospital. It i... essentially a method of curing out of income.

At any one moment the action of radon is precisely the same as that of a certain amount of radium, but there is this essential difference: that the amount is always diminishing. The effect of this will be clear from the chart, where it will be seen that in 3.85 days the value is down to one-half, in nine days to one-fifth. This can, however, be neutralized by starting with a larger dose, and it is a useful practical rule that the total radiation of 1.5 millicuries of emanation is physically almost the same as that from 1 milligram of element in a period of eight days.

APPARATUS AND MODES OF APPLICATION.

We must now turn to the apparatus used in the application of radium and to the methods by which it is applied. The apparatus itself is of the simplest description, and consists chiefly of needles containing radium element and seeds containing radon gas. Flat applicators are also used in the treatment of skin conditions, but these concern the dermatologist rather than the surgeon.

Needles are small platinum tubes varying in diameter from 1.5 to 3 mm., with a point tipped with iridium, and an eye through which a stout silk thread can be passed. A small cavity occupies the whole of the needle except the eye and the point, and this is packed with insoluble radium sulphate, the utmost care being taken to secure absolute uniformity in packing. The wall of the needle should be not less than 0.5 mm. in thickness, so as to cut off the whole of the beta rays. The length of the needle will vary with the requirements of the case. At the London Hospital our needles are 2, 3, 4, and 6 cm. in length, and we have the convenient arrangement that each needle contains one milligram of radium per centimetre of length.

Seeds are minute capsules containing radon gas. Usually the gas is sealed up into a tiny glass capillary, which is then inserted into a tube of platinum, gold, or silver, to cut off the beta radiation. Theoretically platinum is the most efficient screen, but personally I have found silver screens entirely satisfactory. Silver presents the advantages that it is cheap and easily worked, and I have recently elaborated a plan by which the radon is drawn directly into a long silver tube, which is then cut up into suitable lengths. The method of cutting ensures an absolute seal, and the saving of time and trouble, and of personal risk to the laboratory assistant, is considerable.

These needles and seeds provide small sources of gamma radiation, which may be either introduced into the tissues or fitted into external applicators.

Introduction into the tissues is controlled by the empirical observation that the gamma radiation from a milligram of radium can in a period of about five days destroy the cancer cells in a cubic centimetre of tissue. The total amount of radium required in milligrams is thus the volume in cubic centimetres of the tissue to be irradiated, although in the case of large growths, from the effect of cross radiation, a smaller amount will suffice. It must be distributed evenly, the needles or seeds being placed about two centimetres apart, and it must be placed chiefly in the growing edge of the tumour. The needles are attached to stout silk threads, since they contain radium element, and their loss would be disastrous. The seeds may be attached to fine silk threads and be removed later, or they may be simply inserted and left in the tissues, where in most circumstances they do no harm. The insertion of seeds is less likely to be followed by the slight sepsis which sometimes follows the insertion of needles, whilst they have the great advantage that the patient can go home. The action of the needles is, however, uniform, and not diminishing, and on this account they are preferred by some surgeons.

The treatment of a case of carcinoma of the breast furnishes an excellent example of the introduction of radium needles. We may describe the arrangement worked out by Mr. Keynes at St. Bartholomew's Hospital, which has given brilliant results. Two groups of needles are inserted into and beneath the tumour itself on differ...

planes; two rows of needles follow the lymphatics along the borders of the two pectoral muscles; a third group occupies the axilla; a fourth is inserted beneath the clavicle in the region of the costo-coracoid membrane; a fifth is placed above the clavicle; and a sixth group is inserted one in each of the upper five intercostal spaces and one in the rectus sheath. The actual number of the needles will vary between forty and fifty with the dimensions of the breast and of the tumour, and the total amount of radium between 75 and 100 milligrams. The needles are left in place for from seven to nine days and are then removed.

The tongue is an ideal site for the use of seeds. About eight or twelve are required, each containing from 1 to 2 millicuries of radon gas, and they are inserted into the base of the growth, usually through the tongue itself. In this way the actual growing edge is subjected to an intense cross-fire radiation, whilst, as access is obtained directly through the soft tissues of the tongue, the treatment of growths far back, in situations quite inaccessible to ordinary surgery, is perfectly simple. In most cases the tumour will disappear by magic and three weeks later it will have been replaced by a contracting scar. The glands on both sides of the neck are now dissected out in the most thorough manner, and three weeks later the treatment is completed by the external application of radium needles mounted on a thick wax collar made of Columbia paste.

For the irradiation of tumours or of glandular deposits by external application, it is essential that the radium should be supported at some distance from the skin, as otherwise certain areas of the skin will receive a dose which they cannot tolerate and will break down. A convenient plan is to mould a sheet of Columbia paste, a mixture of beeswax 100, paraffin wax 100, and pine sawdust 200, to the region. The wax should be 1.5 centimetres thick, and on its outer surface radium needles should be planted, screened in the ordinary way with 0.5 mm. of platinum. Small needles containing from 0.5 to 1.5 mg. of radium should be distributed at a distance of 1 cm. apart over the surface, whilst special regions, such as the eye or nose, can be protected by the introduction of thin lead plates into the wax mould. The whole appliance should be covered with a thin sheet of lead for the protection of the nursing staff. Even more convenient than wax in many cases is a sheet of spongy rubber; it has the great advantages of lightness and adaptability, and the needles are easily attached to it by strapping. The period of application varies with the strength of the needles and the requirements of the case, from a few hours to a month.

The most dramatic method of applying radium is by the concentration of several grams into a "radium bomb," which is virtually used as a source of intensely hard x rays, the patient being placed at a distance of a foot or more from the centre of the bomb. In the arrangement devised by Dr. Cheval of Brussels 4 grams of radium are embedded in the centre of a hugh block of lead weighing over a ton and supported on steel girders in the ceiling of one room and the floor of the room above. A double cone cut in the lead allows of the exposure of two patients to intense gamma ray radiation, one above and one below. So long as the attendants keep outside the cones, which are marked out by circles on the floor and ceiling, they are perfectly safe, whilst by an ingenious arrangement the radium itself can retire into a recess in the lead block or be advanced to the centre of the cone. The method is costly and very extravagant of radiation, but the results are said to be extremely good.

THE CLINICAL RESULTS OF TREATMENT BY RADIUM.

Turning to the clinical aspects of radium, brilliant results have been obtained in the treatment of rodent ulcer, of carcinoma of the cervix uteri, of carcinoma of the tongue and buccal cavity, and of carcinoma of the breast, in this historical order. It is now being applied in almost every region where cancer develops, and I feel convinced that complete success is only a matter of time. Every region presents its own peculiarities and its own difficulties, and methods which succeed in one region or with one type of growth may fail in another. The mere external application of radium may suffice to destroy a rodent ulcer or a carcinoma of the cervix; it will be futile in the case of the mouth or the breast, where much more drastic methods are required. To show, however, the range of its power I propose to describe very briefly a few of my own cases, making no claim that the results are permanent or that the methods which I have used are the best. The cases do, however, in my opinion, fairly represent the results which one may expect.

Carcinoma of the Palate.

A man of 55 came to see me last April complaining of a discomfort in the palate of three weeks' duration. At the junction of the hard and soft palate, and extending on to both and on to the alveolar margin, on the right-hand side, was a hard nodular mass of ulcerated fungating carcinoma. There was a large mass of hard glands in the right anterior triangle of the neck. The tumour was destroyed with my steam cautery, and the glands were dissected out completely. Healing was perfect in a fortnight, but three weeks later the tumour recurred.

In May I inserted into the base of the tumour six radon seeds, each containing 1.5 millicuries of radon. In fourteen days the growth had disappeared, and was replaced by granulations, in three weeks healing was complete, in six weeks there was no trace even of a scar, and he was wearing his toothplate. He remains in perfect health, with no sign of recurrence.

Epithelioma of the Lip.

A man of 65 was sent to me last September with a huge mass of growth involving the whole of the lower lip and extending almost to the chin. It had started a year previously as a small nodule at the left corner of the mouth. Six needles, each 2 cm. long and containing 2 mg. of radium, were inserted into the lip along the margin of the growth, and were left in place for a week. In three weeks the great bulk of the growth had disappeared, but a week later two small nodules still remaining were treated by the insertion of small radon seeds. A fortnight later the glands were cleared out from both submaxillary triangles, and as the margin of the lip was very ragged a narrow strip was taken from it. In such an advanced case a permanent cure is too much to expect, but the immediate result was remarkable, and from the cosmetic point of view it was extraordinarily good. A remarkable feature was the reappearance of a lip apparently destroyed by carcinoma, demonstrating conclusively the selective action of the radiation employed. No visible carcinoma remained, and, should recurrences appear, they can probably be dealt with by similar means.

Carcinoma of the Thyroid.

A lady of 70 came to me last September with the history that a small swelling, which had always been present in the neck, had for five weeks been growing rapidly, and was now producing severe respiratory obstruction. There was a hard nodular swelling involving both lobes of the thyroid, with several hard glands adjacent to it. It was fixed to the trachea and attached to the skin. It was regarded by myself and by Mr. Hayward Pinch as a typical carcinoma of the thyroid. It grew so rapidly that in ten days the circumference of the neck had increased by 1½ in. Twenty radon seeds, each containing 1.5 millicuries of radon, were inserted through two small punctures, one on each side of the trachea, and were distributed as far as possible throughout the tumour. In ten days the tumour had completely vanished, and although the neck was very thin the thyroid gland could no longer be felt. The circumference of the neck had diminished by 3 in., and all symptoms of obstruction had disappeared. She remains in perfect health.

Carcinoma of the Oesophagus.

A man of 72 had suffered from increasing difficulty in swallowing for three months, and he could now only swallow sips of water with great difficulty. A tall, powerfully built man, he had lost 3 st. in weight, and he was so weak that he could scarcely stand. An x-ray film showed that the oesophagus was obstructed by a malignant growth ten inches from the teeth. On oesophagoscopy a large ulcerated mass of growth was seen encircling the oesophagus, bulging prominently inwards on the left side. Into the substance of the growth eight radon seeds were inserted, each containing 1.5 millicuries. In twenty-four hours there was a distinct improvement in swallowing, which may, however, have been due to the passage of a bougie at the operation. In a week he was taking ordinary soft foods, and was obviously gaining weight and strength. In four weeks he was taking an ordinary full diet, with the sole precaution that he should eat slowly. In six weeks he had gained nearly 2 st. in weight, and appeared to be in perfect health.

Carcinoma of the Stomach.

A man of 53 had complained for three months of epigastric pain, increased by food, of loss of appetite, and of loss of weight, which he estimated at 2 st. On exploration a firm, smooth oedematous tumour of greyish colour was found involving the lesser curvature, and extending upwards almost to the cardiac orifice. It was regarded as a carcinoma of a rapidly growing type, and it was obviously quite inoperable. There were, however, no enlarged glands. Into the substance of the tumour were inserted six platinum needles, each 4 cm. long and containing 4 milligrams of radium element. They were so arranged as to radiate from a centre on the anterior surface of the stomach, and the threads collected here were buried in an invagination of the anterior wall of the stomach, formed as for a Witzel's gastrostomy. The threads were brought out in a bunch through the laparotomy

opening, which was then closed. Five days later the needles were withdrawn without difficulty. The patient made a normal recovery: his pain ceased, his appetite returned, and in three months he had regained his normal weight and was the picture of health.

Angioma of the Meninges.

A man of 45 had suffered for years from fits at long intervals. Recently the fits had become more frequent and severe, and they were now accompanied by loss of consciousness. They were Jacksonian in type, commencing in the left hand and spreading to the face and leg. Beyond a slight increase in the deep reflexes on the left side there was little to be made out on a neurological examination. On exposing the right Rolandic area by means of an osteoplastic flap formed with my craniotome, and on opening the dura, a mass of huge interlacing veins was found occupying the whole of the upper portion of the field, and forming a vascular tumour about three inches in diameter. As no direct treatment seemed practicable the dura was closed, and on to its outer surface were sutured six radium needles, each 2 cm. long and containing 2 mg. of element. The needles were arranged as the spokes of a wheel, and the attached threads were brought out through the central hole in the bone flap. The bone was replaced, the threads were brought through the scalp flap, and the scalp was sutured into position.

The after-history of the case was somewhat remarkable. Three days later he noticed a weakness of the left arm, which developed next day into a complete paralysis. On the following day the needles were drawn out by the threads without difficulty, having been in position for five days. A week later he had completely recovered the use of the arm. There has been no recurrence of the fits, and he seems to be in perfect health.

These cases are only chosen to show the effects which radium can produce in a great variety of situations, and under conditions where the ordinary methods of surgery are not applicable. The brilliant work of Regaud in Paris, of Hayward Pinch and his assistants at the London Radium Institute, of Keynes at St. Bartholomew's, of Cade and his colleagues at Westminster, of Birkett of Manchester, and of many others, has shown that in cancer of the uterus, of the skin, of the breast, and of the mouth and tongue, success can be depended upon as a routine. It has rather been my aim to show how wide are the powers of radium, and that where we have failed it is rather our method of application than our weapon itself which is at fault. I am convinced that we are only on the threshold of a great adventure; I feel that a new world of surgical technique is opening before us; I am beginning to believe that at last we hold in our hands the key to the cure of cancer.

SOME EFFECTS OF DEEP X RAYS UPON THE CELLS OF THE BLOOD.

A PRELIMINARY NOTE ON A PHAGOCYTIC TEST.

BY

F. A. KNOTT, M.D., M.R.C.P., D.P.H.,
HAEMATOLOGIST TO GUY'S HOSPITAL;

AND

W. L. WATT, C.M.G., M.D.,
SURGEON IN CHARGE OF DEEP THERAPY DEPARTMENT, GUY'S HOSPITAL.

THE experiments about to be described are the result of an attempt to observe *in vitro* the effect of the rays employed in deep *x*-ray therapy upon the living cells of the blood. The rays used were the hardest that it has been possible to generate up to the present. The apparatus used was the latest type of constant potential generator with valve rectification, voltage 220,000, metalix water-cooled tube, filtration 1 mm. copper and 3 mm. aluminium.

That these rays have a destructive effect upon living cells is too well known to need discussion here. It is not clear, however, whether such rapid disappearance of white blood cells as occurs, for example, in cases of leukaemia undergoing deep *x*-ray therapy can be accounted for purely by this destructive effect on the cells themselves, or whether other factors come into play. It is more than probable that whatever direct injury occurs to the cells is caused by the secondary rays thrown out by all elements of sufficiently high atomic weight which obstruct the path of the original hard rays in their course through the body. The greatest cell destruction would then occur in the neighbourhood of foci producing these secondary rays, and the importance of this factor was clearly brought out in our first experiment.

A large block of clean paraffin wax was cast with outside dimensions of approximately 6 in. by 4 in. by 4 in. The block was divided longitudinally so as to form a close-fitting lid over a little central chamber hollowed out in the lower half of the block. The capacity of the chamber was about 2 c.cm. Freshly drawn, oxalated blood could be placed in the chamber and submitted to controlled irradiation.

The methods used in examining the blood will be described in the next paragraph. For the moment the important point to note is that if blood was placed in the simple paraffin block described, practically no lethal effect could be produced upon the blood within one and a half hours, however intense the irradiation. If, however, the little central chamber was surrounded by a layer of material relatively opaque to *x* rays, damage to the cells was very soon apparent. The most satisfactory method of producing secondary rays near the blood was found to be surrounding the little chamber within the paraffin block with a layer of blotting paper soaked in a solution of metallic salts, so that the paper was covered with a thin layer of wax and was separated from the blood only by this layer. Before the metal-containing paper was inserted, blood from cases of splenomedullary leukaemia placed in the chamber was submitted to full radiation for two hours—about six times the therapeutic deep therapy dose—but no definitely lethal effect upon the white cells could be detected. When the paper was inserted, damage to the cells could be observed after only fifteen minutes' similar irradiation. The more closely the chamber was surrounded by metallic salt—in other words, the more intense the secondary radiations—the more quickly were the white cells affected.

Methods of Observing Damage to Cells.

To examine individual blood cells while the blood was being irradiated in the chamber small samples were removed at intervals and thin films spread. These were stained by all the usual histological methods, but no certain differences could be made out to distinguish normal from damaged cells. The oxidase reaction was applied to the films and vital staining with cresyl blue attempted, but again no differences could be demonstrated. The only positive results were obtained when samples of blood, before and after irradiation, were kept under sterile conditions at laboratory temperatures up to three days, at the end of which wet film preparations stained with neutral red were made. It then appeared that nuclear degeneration had occurred more quickly in the irradiated white cells. But the differences were not sufficiently sharp to justify the method for quantitative purposes. It must also be explained that blood counts performed upon the samples of blood in the chamber during and many hours after irradiation showed no reduction in the number of red or white cells present. Furthermore, prolonged agitation of the blood in a mechanical shaker did not result in any breaking up of irradiated cells. In short, no actual reduction of the number of cells, red or white, in the blood could be demonstrated and no changes in staining reaction detected.

The Phagocytic Power of White Cells.

It seemed, therefore, that, in order to demonstrate the cell damage caused by the rays, some direct biological method must be used. Experiments were then made upon the phagocytic power of the white cells towards staphylococci, and this method has, we think, given definitely promising results.

Using a marked teat pipette, small equal quantities of blood were drawn during irradiation from the chamber at five- or ten-minute intervals, and to each was added the same amount of an emulsion of staphylococci in 1 per cent. citrate in normal saline. After allowing these mixtures to remain in the 37° incubator for five to ten minutes films were spread and stained with Leishman's stain, the whole procedure following the lines of an opsonic index determination. Direct examination of the films gave a reading of the percentage of white cells in any particular sample still retaining their phagocytic power. Loss of this power was taken to indicate a lethal effect upon the white cells.

The important points noted as a result of this experiment are as follows:

(*a*) If a normal or leukaemic blood be placed in the chamber and irradiated as described, complete loss of all phagocytic power in the polymorphs is observed within about thirty-five minutes.

(*b*) This loss of phagocytic power appears to be quite permanent. The experiment was varied in different ways and samples of blood given time to recover before examination, but no return of phagocytic power could be detected.

(*c*) In passing, it was noted that in fresh unirradiated bloods phagocytic power was possessed only by the relatively mature forms of polymorphonuclear and hyaline leucocytes. It is of interest that myeloblasts, myelocytes, and transitionals appear to have no phagocytic power towards the usual types of bacteria.

(*d*) The lethal effect appeared to begin upon the polymorphs at about the same point, whether in normal or leukaemic bloods.

Thus the experiments with the paraffin block appeared clearly to demonstrate a directly destructive effect by the rays on the white cells, and also that this destructive effect was produced mainly, if not entirely, by the secondary radiations and not by the original hard rays.

Some success with this method *in vitro* at once suggested applications of the test for phagocytic power upon the white cells of patients undergoing deep therapy treatment.

Direct Tests upon Irradiated Patients.

In this respect the first fact to be observed was that if blood from a leukaemic patient be taken twenty-four hours after deep therapy treatment and, as already described, mixed with staphylococci, a considerable number of the polymorphs, although they stain quite normally, will be found to have lost their phagocytic power. The test was therefore systematically applied to patients during actual irradiation. It was found that, whatever part of the body was irradiated, within about twenty minutes the percentage of actively phagocytic polymorphs began to fall. If the test was repeated at intervals a few other important points could be noted—namely:

(*a*) After full irradiation of the spleen in, for example, a case of splenomedullary leukaemia, although the first treatment will result in loss of phagocytic power in a considerable number of the polymorphs, the percentage varying according to the dose given and the width of the field irradiated, the proportion of white cells which disappear from the circulating blood within the next few hours is much less than this, and it takes a few days for all these damaged cells to be removed from the circulation.

(*b*) While the damaged cells are disappearing, a number of new normal polymorphs are being produced, so that a point is reached at which production and destruction balance each other and the immediate fall in the white count ceases. In some cases it may rise again slightly, and a test of the phagocytic power of the cells then shows that the rise is due to fresh normal cells.

(*c*) If these irradiated cases be, however, further watched it will often be found that although all the damaged non-phagocytic cells have disappeared from the circulation and a secondary rise, as above described, may even have occurred, still the fall in the white count continues. At this stage all the cells are normal in their phagocytic power, and the falling count can be accounted for only by some directly depressant action possessed by the rays upon the source of the cells—namely, the reticulo-endothelial system.

In short, it is evident that we can account for most of the immediate fall in the white count of irradiated cases of leukaemia by the directly lethal effect of the secondary radiations upon the blood cells themselves. But the more gradual later fall probably arises from depression of the white cell producing mechanism. Much further work must be done to confirm and elaborate such points as these, but the initial facts are put forward to illustrate the way in which the methods described appear to throw some light upon the mechanism of the deep *x*-ray treatment of leukaemia.

Irradiation and Normal Blood.

Let us next consider the effect of deep therapy upon the cells of patients showing a normal blood picture. Here, again, according to the intensity of the irradiation which their lesions have required, there is also a fall in the phagocytic power of their polymorphs and a gradual removal of the damaged cells from the circulating blood. This effect lasts for a few days, until, reproduction of new cells becoming gradually more effective, the white count slowly returns to normal.

It will at once be clear, however, that the ordinary methods of blood counting in any of these cases do not, at any particular moment, tell us how many of the patient's leucocytes are normal effective cells. Some such test as we have described must be applied before we can be sure they are functionally normal. We believe, therefore, that the test of phagocytic power in the polymorphs may have useful clinical application in the case of patients treated with deep therapy or other irradiation. Whether the results will be helpful in diagnosis and prognosis is at present under investigation. Meanwhile it may be worth while to note the following points.

The first concerns the known fact that actively septic patients, leukaemic or otherwise, are not usually favourable subjects for irradiation. The septic element often becomes more pronounced, and the demonstration of the rapid disappearance of phagocytic power in the leucocytes of these patients throws some light upon this antiseptic failure. If these patients must be irradiated, it is well to apply the test for phagocytic power so that this function of their white cells shall not be driven too low. For this purpose an ordinary white count is not sufficient.

Secondly, it is clear that the initial fall in a patient's white count, following irradiation, is a function of the number of directly damaged cells. By noting the loss of phagocytic power, even while irradiation is actually taking place, we can make an immediate estimate of what the fall in the white count will be and control the dosage accordingly. Using ordinary methods of blood counting, this fall has actually occurred before we can estimate it. Furthermore, in patients whose white cell count is already low, and in whom it is undesirable to cause too great a fall, a useful method of controlling dosage and of forecasting the white cell loss is the application of the phagocytic test. Irradiation may well be stopped at a point where not more than 25 per cent. of the patient's polymorphs have lost their phagocytic power. Any future irradiation would depend upon the restoration or otherwise of phagocytic power.

Summary.

A method is described of estimating the phagocytic power of the polymorphs in patients undergoing deep *x*-ray treatment, and some possible clinical applications of the test in treatment control are put forward.

Some results with the test are discussed in relation to the theories concerning the effects of irradiation upon leukaemic and other patients.

TONSIL PUNCTURE: A NEW METHOD OF INVESTIGATION.

BY

JEFFREY RAMSAY, M.D., AND C. M. PEARCE, M.B., M.R.C.P., F.R.C.S.,

HONORARY PHYSICIAN, HONORARY ANAESTHETIST,

BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY.

DISEASE of the tonsils, as a clinical entity, has been known for many centuries. Celsus, who was born in Rome about the time of Christ, devotes a whole chapter to the subject in his *De Medicina*, and makes many references to tonsillar diseases in other portions of the work.

In our day acute and chronic affections of the tonsils rank among the diseases which are frequently encountered. The work which follows is concerned with the modern viewpoint of the tonsil as a source of focal sepsis. Among such sources the tonsils occupy an important position. Our present investigations have convinced us that this importance has not been exaggerated and that hidden infection in the tonsils may be responsible for much ill health, both definite and indefinite. Irwin Moore[1] gives a list of fifty-one diseases which may result from focal infection of tonsillar origin. The results of such infection may reach and affect any part of the body by way of the lymphatics or the blood stream. Moore states that the general opinion is that after the age of 5 years nearly all tonsils are

useless and are in the majority of cases a menace to health.

The tonsils are examined in every case when a search is being made for a possible source of focal sepsis in a patient, and it is a common experience to discover a tonsil or tonsils which can only be described as "doubtful"—that is, it is difficult to say if we are justified in advising their retention or their removal. The tonsil may even be small and fibrosed, and yet may be a potent source of trouble.

Although much may be learned by an experienced observer from an inspection of the tonsils *in situ*, and from any history which bears upon them, the standards of assessment as to their normality or otherwise have been somewhat arbitrary hitherto, and the personal factor must of necessity play a part in the examining physician or surgeon. We have tried to arrive at a more accurate estimate by means of direct puncture into the substance of the tonsil, with subsequent investigation of the aspirated material on lines which have been standardized.

Reasons for the Procedure.

In order to make clear our reasons for this scheme it is necessary to refer briefly to the structure of the normal tonsil and its alteration in chronic inflammatory disease. A normal tonsil consists of a mass of lymphoid tissue covered on its free surface with the stratified epithelium of the mucous membrane. Its surface is pitted with apertures leading into crypts, which are lined by a prolongation of the stratified epithelium of the surface, and into them the ducts of numerous small mucous glands open. The lymphoid tissue of the tonsil is at intervals aggregated into nodules, in which the lymph cells are more closely arranged than elsewhere. In the centre of these nodules active multiplication of the lymph cells occurs. In the lymphoid tissue are numerous blood vessels and lymphatic channels.[2]

In chronic inflammatory disease the appearances are changed. We find that the chief histological differences are in the crypts and in the epithelium of the surface. The continuity of the stratified epithelium of the crypts is frequently broken at the base of the crypt. In some instances there is a band of fibrous tissue around the crypt, lying close to the surface of the stratified epithelium which lines the crypt—a protective phenomenon in response to constant irritation in the crypt—and this fibrous band, like the stratified epithelium, is frequently broken at the bottom of the crypt. The epithelium on the general surface of the tonsil is rarely intact in such cases, and sometimes there are small areas of ulceration on this surface. The significance of such solution of continuity in the stratified epithelium is obvious. Organisms can obtain a free entrance directly into the tonsillar substance, and they can escape easily in a reverse direction, from the tonsil into the mouth, and be swallowed with the saliva.

Other pathological points which we have noted are a thickening of the capsule of the tonsil; an increase in the interstitial connective tissue, especially in the immediate neighbourhood of the crypts; and sometimes an increase in thickness of the walls of the vessels, affecting chiefly the fibrous layer of the wall. In sections stained by Gram's method it was difficult to pick out organisms, but some short-chained streptococci were occasionally seen in the part of the tonsil near to a crypt; in some cases there were minute abscesses immediately under the capsule; no tonsillar calculi were found.

In view of these findings we repeat that an inspection of the tonsil leads us only part of the way along the track. Particularly if Eve's suction method is employed, it is not unusual to see a crypt or crypts filled with a yellowish mass of micro-organisms or food debris. Although this might be one of the points in favour of condemning the tonsil, it must not be forgotten that this crypt may be intact at its base and may be almost, if not entirely, impervious to the entry of micro-organisms. In fact, the onward march of the latter may actually have been easier in a neighbouring wide-mouthed but empty crypt. The bacteriological investigation of a crypt may therefore be rather a hindrance than a help in determining the true condition of the tonsil. Since it is recognized also to be useless, from a bacteriological standpoint, to rely on cultural results from swabbing the surface of the tonsil, except in such conditions as diphtheria or Vincent's angina, we have adopted the plan of deep puncture into the substance of the tonsil.

Technique of Tonsil Puncture.

(*a*) *Apparatus Required.*

A supply of Bonain's solution, which consists of cocaine hydrochloride, menthol, and pure carbolic acid, 1 gram of each; a probe or forceps for a small pledget of wool, with which this solution is applied to the tonsil; a tongue-depressor; an all-metal syringe with guarded needles, made for us for this purpose by Messrs. Allen and Hanburys, and a test tube containing 5 c.cm. of sterile bouillon.

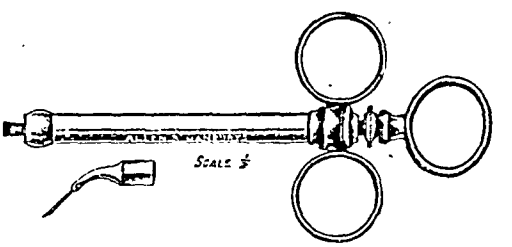
(*b*) *Procedure.*

The operator, wearing a head-mirror, sits facing the patient, and a good light is reflected on to the mirror from a lamp behind the patient's head. The tongue-depressor is inserted and the tonsils are examined. The anterior pillar of the fauces may be pressed upon by another spatula held in the operator's left hand, as recommended by Irwin Moore, thus enabling a thorough inspection of each tonsil to be carried out. After selecting a spot for puncture, which should be preferably in the fleshy portion of the tonsil, away from a crypt, the tongue-depressor is withdrawn.

A pledget of wool is twisted on to the probe or forceps and dipped lightly into the bottle of Bonain's solution. Before withdrawal the wool should be squeezed gently against the side of the bottle in order to get rid of any superfluous solution, which might drip in the patient's mouth.

The tongue-depressor is reinserted and the selected portion of tonsil is swabbed with the pledget of wool steeped in Bonain's solution, the carbolic acid in which makes the surface of the tonsil as aseptic as may be possible. The syringe, with its needle attached, previously sterilized by boiling, is taken in the operator's right hand. The piston is withdrawn about one-eighth of an inch, and is pressed home as the puncture is made. The positive pressure thus obtained tends to dislodge any organisms which might find their way into the needle as it goes through the surface of the tonsil. The needle is pushed into the tonsil as far as it will go; the distance from the point of the needle to its guard is three-eighths of an inch. Once in the tonsil the needle is rotated in various directions, the operator meanwhile exerting gentle suction by withdrawing the piston slowly. After four or five seconds the needle is withdrawn from the tonsil, and care is taken that the needle shall not touch any structure in the mouth during its withdrawal.

The syringe, with the needle attached, is introduced into the test tube containing the sterile broth. The point of the needle should come to a halt about an inch above the surface of the broth, and the piston is then pressed home firmly and quickly. The result is a jet of air, with pus or debris, which is



deposited on the wall of the test tube. Sometimes a definite bead of thick pus is seen, in other cases a small spray of greyish-white material is all that is visible. This material on the wall of the tube is inspected with the naked eye, and the broth is then shaken up so that it becomes thoroughly impregnated with the material which has been shot from the needle.

In rare instances nothing appears to come from the needle when the piston is pushed home. If this is the case, the needle should be introduced into the broth, and some of the latter should be sucked into the syringe and then be ejected. It is advisable to investigate both tonsils, as we have occasionally found one to be sterile and the other to be infected.

The wool plug of the test tube is flamed and replaced; the tube is labelled and put into the incubator, or kept in a suitable warm atmosphere for at least twenty-four hours. A smear from the culture is then stained and microscoped.

Results of Culture.

We have examined 158 tonsils by this method of puncture, the ages of the patients varying from 5 to 51 years. Of these tonsils 17 were found to be sterile on culture.

The following is a list of the organisms obtained from the remainder:

Streptococci were present in pure culture in 111 cases, and with other organisms in 26 cases. Using fermentation tests on the lines suggested by Mervyn Gordon, 81.2 per cent. gave the reactions for *Streptococcus pyogenes* and 18.8 per cent. gave the reactions for *Streptococcus viridans* or *mucosus*; 56.5 per cent. of the streptococci were facultative anaerobes, and 78 per cent. gave a haemolytic reaction on haemoglobin agar.

Diphtheroids were present in 4 cases; staphylococci in 18 cases (3 in pure culture); pneumococci in 5 cases (1 in pure culture); *B. influenzae* in 1 case. One patient who showed staphylococcal infection of the tonsil was suffering from sties and from a pustular eruption on the ear.

It is of interest to note that in two of the cases which were found to be sterile on puncture the patients had suffered from an acute inflammation in the tonsil about three weeks before the puncture was made. The inflammatory process had evidently acted as an efficient, though perhaps temporary, sterilizer of the tonsil.

We have found that little, if any, useful information can be obtained by direct examination of a smear obtained by tonsil puncture. Pus and epithelial debris are frequently present, but it is rare to find organisms in the smear itself.

The Blood Immunity Test.

If after thorough exploration with a needle in the manner which has been described there is no growth of organisms in the broth it appears to be reasonably probable that the tonsil in question is not a source of danger to the patient. But even if organisms grow in profusion in the broth, this is no proof that they are harmful to their host. We therefore pass on to the second stage of the investigation. The work of Solis-Cohen and of Cronin Lowe[3] has emphasized the importance of testing the immunity of the patient's own blood towards organisms obtained from some site of possible infection in his body.

Given accurate standards, with due care in obviating the effects of mass, it appears reasonable that a man's own blood should contain sufficient immune bodies to deal with a small number of organisms from his tissues. In order to obtain correct comparisons with which to work, the following plan was adopted.

A broth culture of streptococci was diluted with more broth until its opacity, after shaking up, was equal to that of a 2,000 million vaccine, and this standard is the one which we always use; 5 c.cm. of supposedly healthy human blood were run into each of five sterile test tubes. The blood in the first test tube was inoculated immediately with three platinum loopfuls of the above culture. The blood in the second tube was inoculated with 0.01 c.cm. of the culture; in the third tube with 0.02 c.cm.; in the fourth tube with 0.1 c.cm.; and in the fifth tube with 0.2 c.cm. Subcultures into broth were made from each tube the next day. It was found that the first tube, inoculated with three platinum loopfuls of the culture, was sterile: but the other four tubes showed a growth of streptococci on subculture. In them the effect of mass was felt.

We have adopted the three loopfuls standard, using a loop of the size shown ○, in testing the effect of his own culture on the resisting power of the patient's blood. We realize that such a standard is not infallible and that it may vary, temporarily or permanently, both as regards the immunity of the "normal" blood and the virulence or otherwise of the strain of organism used in testing. If growth occurs the supposedly normal individual may himself be harbouring, for example, a streptococcal infection. But we have found the three loopfuls to be a good working basis, since, as will appear later, a certain number of patients with infected tonsils can inhibit this strength of their own culture.

To sum up, the broth tube containing the material obtained by tonsil puncture is incubated for twenty-four hours. A film is then stained, and the organisms, if any, are identified. After taking the usual precautions in sterilizing the skin, a sterile needle is inserted into the median cephalic or median basilic vein of the patient, and 5 c.cm. of blood are run into a sterile test tube. This blood is inoculated immediately with three platinum loopfuls of his previously diluted culture; it is then incubated for at least twenty-four hours, and three platinum loopfuls of it are then subcultured into sterile broth. If the organisms originally present in the culture from the tonsil are found to have grown in this subculture, it is presumptive evidence that the resisting power of the patient's own blood is defective as far as the tonsillar organisms are concerned.

It happens not infrequently that more than one organism is present in the tonsil culture. In such cases the blood sometimes exercises a selective power, destroying one organism but failing to inhibit the other. The whole procedure which has been described is in reality quite simple, and can be carried out by any practitioner who is possessed of a suitable syringe, a supply of sterile broth, a platinum loop, and an elementary knowledge of bacteriology. Far from objecting to the investigation, we find that patients welcome it when its objects are explained to them. They realize that a thorough examination has been made, and for this reason they are more willing to submit to a subsequent operation if this is found to be necessary.

In trying any new method mistakes have to be rectified and alterations in technique have to be made. We propose, therefore, for the present, to refer only to the last 50 instances in which this procedure of blood inoculation has been carried out. All the cases showed signs or symptoms which justified an exploration of the tonsils. In these 50 instances the blood was sterile in 11, and grew organisms from the tonsil culture in 39. Neither the age of the patient, nor the sex, nor the type of organism appeared to have any effect as regards the immunizing power of the blood.

If the tonsil is found to be infected, and the patient suffers from such a condition as an arthritis for which no other focal cause can be found, and yet his blood possesses sufficient immunizing power to destroy the organism from the culture, we have had good results from the use of an autogenous vaccine, prepared from the tonsil culture. In this case, of course, the result may be due to non-specific protein shock.

Discussion of the Method.

It will be noted that the relation of adenoids to focal sepsis is outside the scope of our present investigation, which deals only with the method of tonsil puncture. If the tonsils have been found to be diseased and have been removed, the question of the results of the operation is also hardly germane to the present thesis, though it is tempting to record in detail the relief of symptoms and the mental and physical improvement which have almost universally followed the operation. To those patients in particular who have been just within the borderline of ill health for many years, with an absence of *joie de vivre*, and with a mental and physical state which was easily fatigued, as well as to those with more definite ailments, such as backache, joint pains, or skin affections, it comes as a surprise to hear that their tonsils have been found to be diseased. Their scepticism has frequently been followed by pleasant relief after operation. The hitherto uninvestigated tonsil has much to answer for.

We do not wish it to be thought that our interest in the investigation of the tonsils has led to any loss of perspective. We realize the importance of, and deal frequently with, such other sites of infection as the teeth, the nasal sinuses, the genito-urinary tract, and the alimentary tract. As regards the teeth, our profession passed through a phase in which wholesale extraction played a not inconspicuous part. Time brought radiography and saner judgement. We hope that the method of tonsil puncture, especially when it is developed and improved, may save unnecessary tonsillectomy on the one hand, and lead to highly necessary tonsillectomy on the other hand.

An interesting question has been put to us by a colleague: Is it possible that the organisms which are hidden in the tonsil may serve a purpose in the production of antibodies and thus help to immunize the individual by a process of auto-inoculation? This question was introduced by Good many years ago in relation to the crypts. If this is so, removal of the tonsils might be undesirable. Such a process may possibly occur in those cases in which the blood is found to be sterile after inoculation with the organisms. But in other cases, where the blood is not able to resist the organism, we believe that removal of the diseased tonsil is sound in theory and in practice.

Although the tonsil may be the chief source from which the organisms and their toxins pour into the blood stream, the other structures in Waldeyer's ring are frequently found to be infected also, as witness the pharyngeal discomfort which may not clear up for weeks or even months in an adult after the tonsils have been removed and the tonsillar fossae are firmly healed.

In view of Rosenow's work on the selectivity of various strains of streptococci, it would be interesting to know if there is any association between hitherto hidden streptococci in the tonsil and streptococci in the appendix, which, from its structure, has been called the abdominal tonsil, and also if such hidden tonsillar infection may be associated with gastric, duodenal, and jejunal ulcers. The occasional occurrence of the latter after gastro-jejunostomy has never, to our knowledge, been explained satisfactorily. In making such a suggestion we are assuming that the teeth and other possible foci of streptococcal infection have received due attention.

At the risk of reiteration we wish to stress once again the fact that a mere inspection of the tonsils in such cases may lead to an error of judgement, whereas tonsil puncture and thorough investigation may throw light on what has hitherto been obscure in the matter of a cause.

Uses and Possibilities of Tonsil Puncture.

We hope that this method of investigation may be of use to the physician who is endeavouring to trace a focal sepsis, which may be chronic in its manifestations, giving rise to such conditions as fibrositis, arthritis, and neuritis; or acute, in the form of a streptococcal septicaemia whose origin may be baffling. It may be useful to the aurist and laryngologist, both in assessing the condition of the tonsil *per se*, and in relation to affections of the ear and larynx which may spread from hidden tonsillar infection; to the general surgeon, for whom the effects of focal sepsis are also important; to the ophthalmic surgeon, since tonsillar infection plays a part in many eye conditions; to the dermatologist, in helping to solve the problem of certain skin affections; to the neurologist and psychiatrist, since it is becoming increasingly evident that many psychoneuroses and true psychoses may be associated with focal sepsis; and to many other branches of our profession.

We ourselves wish to stress its possibilities in connexion with two outstanding diseases—namely, puerperal septicaemia and carditis. Space will not allow us to go fully into this question, but we should like to outline our views.

We believe that many cases of puerperal septicaemia result from auto-infection, wakened into activity by the stress of labour. The teeth, the urine, and other possible sites of infection in a pregnant woman are now examined as a routine, and we suggest that the tonsils should receive more attention in this respect. If, by puncture, they are found to be infected, particularly by a member of the streptococcus group, and if the woman's immunity is found to be deficient on blood culture, we suggest that an autogenous vaccine should be prepared from the tonsil culture and administered at intervals throughout the pregnancy in order to raise the general resistance as far as possible.

In relation to the prevention of carditis we have high hopes of the usefulness of the method.

It will be seen from the figures we have given that the streptococcus is the organism most commonly found on tonsil puncture. This finding may have some bearing on the question of person-to-person infection in rheumatism, since the streptococcus may be air-borne, especially under crowded and insanitary conditions.

In the report of the Subcommittee of Inquiry into Rheumatic Heart Disease in Children[4] we find that "it is universally recognized that the portal of entry of the infecting organism is, in the majority of cases, through the nasopharynx in general and the tonsils in particular." And again, "In spite of certain difficulties, there is no rival to the streptococcic theory of acute rheumatism." Although the additional question of environment as a predisposing cause must not be forgotten, it seems to us that, from the all-important point of view of *prophylaxis*, it is essential to know if the tonsils of a child are harbouring a member of the streptococcus group.

Another significant fact is the age of onset of acute rheumatism. "First attacks of the severer types occur most commonly about the seventh or eighth year of life," and the tonsils appear to lose their usefulness after 5 years of age. From that time it seems that they cease to be defenders and become attackers. We urge, therefore, that the tonsils of children, particularly those over 5 years of age, should receive due attention from the point of view of exploratory puncture. The procedure is not a difficult one and should require only the same degree of tactful handling as is shown by the school dentist, whose visits, at first a source of apprehension, are now tolerated freely. In the case of a very nervous child we would go so far as to suggest that an anaesthetic should be given for the purpose of tonsil puncture.

If the tonsils yield no growth on culture, they are free from suspicion for the time being, though, of course, the question of adenoids must be borne in mind. The lapse of one or two years, or an attack of sore throat in the meantime, are indications for further tonsil puncture. Should the tonsils be found to harbour streptococci, the child is a potential sufferer from rheumatism, and the removal of the tonsils is a wise step, even without testing the resistance of the child's blood to the organism obtained by puncture, since it is not always easy to obtain blood from a child's vein. If the tonsils are found to be infected we can put the position clearly before the parents of the child.

Although tonsillectomy may not entirely prevent rheumatism, the results of the operation are eminently encouraging, and the report[4] states that "in no case did permanent heart disease show itself for the first time in a rheumatic attack after operation."

We hope that if this method of investigation is adopted, with a wide spreading of the net, it may do much to prevent heart disease in childhood. As regards adults, many sufferers from heart disease acquired such disease in their early years. In the future such early acquisition may be avoided, and it may be possible to reduce the general incidence of heart disease in later life if the tonsils receive due attention by puncture, remembering, of course, other foci of infection also. Heart disease, when once it is established, is an end-result. Our plea is for the efficient investigation of one of the principal sources from which it is known to arise, and for the eradication of such a source when necessary as a measure of prophylaxis.

Summary.

1. Hitherto the condition of the tonsils has been judged chiefly from external appearances.

2. A simple method of tonsil puncture has been described. If the tonsil is found to be sterile removal is probably unnecessary.

3. Should the tonsil be found to be infected, the organisms can be tested against the patient's blood and some idea of the resisting power of the latter to the organism can be obtained.

4. If the immunity of the blood is found to be impaired, removal of the tonsils is probably desirable, other things being equal.

5. Uses and future possibilities of the method are discussed, particularly in relation to puerperal septicaemia and to rheumatic carditis in children.

We wish to express our thanks to our colleague Dr. J. M. Wishart, assistant ophthalmic and aural surgeon, Blackburn and East Lancashire Royal Infirmary, for his interest in the investigation and for allowing us to examine suitable cases; also to Mr. H. W. Floyd, of the laboratory staff, for his help in technical matters.

CEPHALIC TETANUS.

BY

JAMES A. JENKINS, CH.M., F.R.C.S., ASSISTANT SURGEON, AND G. M. F. BARNETT, M.B., F.R.C.S., SURGICAL REGISTRAR, DUNEDIN HOSPITAL, NEW ZEALAND.

WE wish to record the following case of head tetanus as it is an uncommon condition, not often reported, and consequently not well known to the profession.

CLINICAL NOTES OF CASE.

A well-developed boy, aged 12 years, was referred on December 15th, 1927, with the following history. A week previously he had been struck with a cricket bat on the right side of the face. The cheek and side of the nose had been bruised, and an irregular wound caused. This had discharged freely, and a splinter of wood had appeared three days after the accident. Five days after the injury facial paralysis appeared on the right side, and the next day he noticed that the jaws were stiff and he could not open his mouth. He rapidly appeared to become very ill, and the rigidity of the jaws had become extreme.

On examination his general appearance suggested an overwhelming toxaemia. He was of a greyish colour, restless, and emotional, and his respiration was slightly laboured, with a rattle due to mucus collecting in his respiratory tract. There was complete facial paralysis on the right side. Trismus was intense, and he was unable to speak or swallow. He had slight spasm of the facial muscles on the left side. The muscles of the neck were not appreciably affected. There was some hypertonus of the arms.

The wound was about half an inch long, and was situated at the junction of the nose and cheek. His temperature was 96.5° F. and the pulse 80. Subsequently the temperature ranged for the most part a degree or two above normal.

Treatment and Subsequent Course of the Disease.

His condition was improved with 10 per cent. glucose per rectum, and three hours after admission, under chloroform anaesthesia, suboccipital cisternal puncture was performed, and 15,000 units of antitetanus serum were injected after the removal of an equal volume of cerebro-spinal fluid. A further 15,000 units were injected into the facial nerve from its exit from the skull to its peripheral distribution near the wound; 20,000 units were given intravenously. The wound was then opened up and eusol dressings were applied. The jaws relaxed under deep anaesthesia, and opportunity was taken to tie corks between the teeth in order that subsequent feeding could be carried out.

During the next twelve hours his general condition improved slightly, and under anaesthesia 20,000 units were injected into the cisterna by suboccipital puncture, 20,000 intravenously, and 10,000 into the facial nerve distribution. He improved still further, though trismus and facial paralysis were unchanged. Swallowing was still difficult.

On December 18th 20,000 units were given intravenously. The next day, though the temperature and pulse were both still high, there was improvement in the general condition. Trismus was still severe, and any interference with the corks between the teeth increased the spasm; though urged to swallow sips of water and milk the patient was manifestly afraid to attempt this. There was no tendency to generalized spasm. Under chloroform anaesthesia 10,000 units of antitetanus serum were given into a vein.

The following day the slight improvement already evidenced was maintained, but fluid by the mouth was piteously refused, the patient being terrified of attempting to swallow. There was a noticeable smell of acetone in the breath, and this remained evident for nearly a week longer, in spite of the fact that copious enemata of glucose and water and of sodium bicarbonate solution were regularly given and satisfactorily retained. On this day, December 20th, chloroform was administered, and 10,000 units were given intravenously, and the opportunity was taken to remove the corks, which were almost bitten through. These were replaced by two round wooden blocks fashioned like little cotton-reels, adjusted between the bicuspid teeth on each side and fastened together by a string behind the head. Improvement was slow, but occurred day by day.

On December 22nd there was complaint of soreness in the shoulders and arms, but no spasm except in the masseter. Under chloroform 10,000 units were given intravenously and 10,000 into the spinal theca by a puncture in the upper lumbar region, after the withdrawal of a corresponding quantity of cerebro-spinal fluid.

On December 24th, 26th, and 28th intravenous and subcutaneous injections of 10,000 units each were given under anaesthesia. On December 29th trismus was noticeably less, and for the first time the patient allowed one to remove the wooden props, and was able voluntarily to separate his jaws half an inch. He took sips of water, and sucked a small piece of orange. The props were replaced for the night.

The next day he was better still, and took a little drink of milk. Barley sugar was given him to suck, and from this time on the starvation acidosis seemed to disappear, and acetone was no longer present in the breath or the urine.

As his confidence in his swallowing powers returned his diet was steadily increased, the wooden props were dispensed with, and he began to speak intelligibly. On account of this rapid improvement it was thought that further administration of serum was not required, but in view of subsequent events this discontinuance, even in face of the steady abatement of symptoms, was probably unwise.

For the first week of January improvement was steady, and the boy began to eat with appetite, indeed almost ravenously, and to sleep soundly for ten or twelve hours at night. He was allowed to sit in the sun on a balcony for an increasing time each day, and then to walk from his bed to the balcony. All this time, though trismus had been abating steadily, the right-sided facial palsy was still complete. In addition, there was a frequent rise of temperature to 99° or 99.6° F., usually in the evening, but sometimes occurring at other times. Accordingly, on January 10th, after an experimental minute subcutaneous dose, 25,000 units of serum were given subcutaneously and intramuscularly with no ill effect, and with a subsequent lowering of the temperature on the next two days. On January 12th 10,000 units were given, also subcutaneously, and on January 16th 10,000 units were given intravenously; following this there were marked anaphylactic symptoms within a few minutes of injection. Abdominal discomfort, vomiting, diarrhoea, pallor, generalized urticaria, and a pulseless condition caused some alarm. Adrenaline, injected at once, was associated with rapid improvement.

The patient was discharged to his home on January 23rd. He could then open his mouth half an inch. The paralysis was not quite complete. He still looked very frail, and his evening temperature was 99° to 99.5° F. During the past two months the paralysis and trismus have completely cleared up. His general health is now good.

We attribute his recovery mainly to the massive doses of serum administered, and more especially to the route used in this particular case. Both experimental and research investigation seem to point to the advisability of getting the serum to the area in which the toxin is concentrated, and in this case it was possible to carry this out very completely. The injections into the cisterna gave a high concentration in the region of the pons and medulla and intracranial course of the seventh nerve. The injection into the facial nerve distribution from the stylo-mastoid foramen to the region of the wound increased the concentration still further. Serum not utilized locally by these injections is absorbed and adds to the effect of the intravenous and subcutaneous doses.

COMMENT.

Cephalic tetanus was first described by Rose in 1872. By 1911 some ninety-four cases had appeared in the literature, and Brown[1] gives an excellent summary of cases reported up to that time. In 84 per cent. of these cases

the first sign of the disease had been trismus, either alone or accompanied by paralysis of one or more cranial nerves. The mortality in which paralysis preceded trismus was 64.2 per cent., as compared with 53.2 per cent. for cephalic tetanus as a whole. Paralysis of the facial nerve was the commonest form of paralysis and appeared on the side of the lesion. Bilateral paralysis had occurred in seven cases, but in all but one the wound had been in the mid-line of the head.

Since this time relatively few cases have been reported. Most of these have been in Continental literature. The rarity of the condition is shown by the fact that the *Medical History of the War*[2] reports only two cases of head tetanus out of 2,529 cases of tetanus occurring on the Western front. A very complete description of head tetanus is given by Courtois-Suffit and Giron,[3] and an admirable illustration by Quervain in *Clinical Surgical Diagnosis*.[4]

The prognosis in head tetanus is, judging from mortality statistics in the cases recorded, much that of the more common generalized form. The incubation period is less, apparently owing to the shorter distance the toxin has to travel, but even with a short incubation period—provided the spasm remains localized to the muscles of mastication—the prognosis is not affected. It would appear that the patient's attention is drawn to his condition earlier in head tetanus, and consequently treatment is more likely to be offered before the toxin has spread to other parts of the nervous system.

ADENOMA OF THE LIVER WITH MALIGNANT CHANGES ASSOCIATED WITH INFANTILISM.

BY

HENRY F. HISCOCKS, M.B., B.S.LOND.,

LATE RESIDENT MEDICAL OFFICER, HORTON GENERAL HOSPITAL, BANBURY.

CASES of adenoma of the liver are uncommon, but the association with infantilism and the development later of malignancy in the tumour make this case of especial interest.

Clinical History.

A domestic servant, aged 19, was admitted to the Horton General Hospital, Banbury, on September 9th, 1927, complaining of vomiting and diarrhoea. Up to the age of 13 the patient had been healthy and of normal growth. Since that time she had ceased to grow, and there had never been any menstrual periods. Mentally she was bright, and up to the average standard at school. In every other way her health was excellent. Three weeks before admission she began to have attacks of vomiting two or three times daily soon after food: this was unassociated with nausea, and the appetite was good. There was no complaint of pain. At the same time diarrhoea came on. The only other symptom was an aching pain in the region of the right iliac fossa, which began the day before admission and aggravated the vomiting; the appetite, however, was still unaffected. There was nothing to note in the past history beyond the arrest of development at the age of 13. She had a mother and father and five brothers and sisters living and in good health.

On examination the patient appeared undersized for her age, her height being 4 ft. 8 in. and the weight 4 st. 10½ lb., but she was otherwise healthy. The eyes were normal. There were a few slightly enlarged cervical glands on both sides, but the thyroid appeared normal. The skin of the whole trunk showed a faint brownish pigmentation. There was no abnormality in the chest. The abdomen moved well on respiration, but was uniformly distended. Pubic hair was present. There was no tenderness. The liver edge was palpable 2½ in. below the right costal margin. The spleen and left kidney could not be felt. In the right flank was a mass of dense consistency, deep to the parietes and *having an irregular craggy surface. Above, it was* continuous with liver dullness; below, it extended to within 2 in. of the anterior superior iliac spine. It was fairly mobile antero-posteriorly and laterally. Above Poupart's ligament on each side irregular craggy masses could be palpated. No free fluid could be detected. Knee-jerks were present and equal. There was no oedema of the ankles. The urine was acid, specific gravity 1020, no albumin or sugar.

The diarrhoea and sickness improved during the first three weeks in hospital, but the abdomen slowly increased in size, the tumours showing no appreciable change. Four weeks after admission free fluid was definitely detected, and after this the girth of the abdomen increased more rapidly. Two weeks later oedema of both ankles developed, *and the superficial abdominal* veins became very dilated.

On October 31st (about seven weeks after admission) the abdomen was tapped to relieve dyspnoea and general discomfort, and 8½ pints of clear sticky light yellow fluid were drawn off. This contained 2.3 per cent. of albumin, and in the centrifugalized deposit were little masses of tissue cells such as might be shed from some growing epitheliomatous structure. On November 11th a further 3½ pints were drawn off. From this time the patient went rapidly downhill, and died, after being comatose for twenty-four hours, on November 17th—ten weeks after admission. Throughout the patient was apyrexial, and the pulse rate averaged 80 to within the last fourteen days, when it ranged between 100 and 130.

Pathological Findings.

Post-mortem examination revealed some clear blood-stained fluid free in the peritoneal cavity. The great omentum was much thickened and enlarged by numerous knob-like deposits of growth, which completely covered its surface. All other peritoneal folds, and the abdominal surface of the diaphragm, were studded with these knob-like masses of growth closely set together. On the right side of the abdominal cavity, extending down from the liver, was an elongated mass about 5 in. long by 2½ in. by 3 in. Its upper pole was embedded in the right lobe of the liver, but marked off from the liver substance by a definite capsule. It was separate from the right kidney and suprarenal. On section it was firm, and had a hard core of fibrous tissue with a small calcified patch in the centre. The liver itself was somewhat enlarged, and showed congestion on *section; there were one or two knobs of growth on its surface.* The gall-bladder was normal. The kidneys and suprarenals were a little congested, but otherwise normal. The pancreas was normal, and the spleen was not enlarged. The pelvic organs were set in a dense mass of knobby growth, which surrounded and pressed on all the vessels. The uterus and tubes, which were dissected out with difficulty, were infantile, and the ovaries could not be distinguished. There was no *retroperitoneal growth. Examination of the brain, head and* neck, and thoracic organs revealed nothing of note.

Dr. A. G. Gibson of the Radcliffe Infirmary, Oxford, very kindly made a histological examination of the growth. The elongated tumour embedded in the liver showed hypertrophied masses and strands of liver substance. At one spot in the capsule of this growth there was evidence of rapid metastasis into the peritoneal tissue. The secondary growth in the peritoneum showed evidence of much more recent and rapid cell formation, and consisted of strands of liver-like cells with a fibrous stroma. There was no resemblance either in the primary or the secondary growth to a suprarenal or a kidney growth.

Comment.

The tumour was presumably an adenoma of the liver with secondary malignant changes. These rare tumours are described as being often congenital, and the structure of this one, with its fibrous and calcareous centre, goes to show that it must have been of slow growth and present for some long time. When they occur, malignant change is not an uncommon sequel.

It was difficult to account for the lack of development, which did not appear to conform to any well-known type. Deficiency of anterior pituitary lobe secretion at first seemed a possibility, but *x* rays showed a normal skull, and *post mortem* there was no macroscopic abnormality of the gland. Moreover, the presence of pubic and axillary hair is an unusual feature of this condition. The thyroid gland was normal in appearance, and in other ways the patient did not conform to the type of under-development associated with hypothyroidism. Renal infantilism was a third possibility, but the urine was always normal, and the kidneys showed no marked change. Chronic diseases in childhood may delay development, and it would seem, therefore, that in this case the infantile condition of the patient is to be attributed to the state of cachexia produced by a long-standing liver tumour.

My thanks are due to Dr. Penrose of Banbury, under whose care the patient was admitted to hospital, for permission to publish this case, and for suggestions in putting together these notes.

Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF HAEMOPTYSIS.

THE method here described for the arrest of haemoptysis by the *supraglottideal injection of adrenaline* was proposed by my assistant, Dr. Giuffrida, in the course of our joint studies on the local treatment of pulmonary tuberculosis. The injection is carried out by means of a 5 c.cm. syringe, to which is fitted a cannula 2 mm. in diameter and 11 cm. in length, of which the distal 4 cm. are bent on the remainder at an angle of 110°. The material injected consists of 1 c.cm. of a 1 per cent. solution of adrenaline, to which has been added 2 c.cm. of boiled water. The patient, who must be in a good light, is asked to breathe as slowly and deeply as possible, while the operator, holding the tongue between the thumb and forefinger of the left hand and the syringe in the right hand, introduces the cannula along the side of the tongue to the epiglottis, and during a deep inspiration injects the solution. The patient's body is now inclined towards the diseased side, so that the drug may be distributed along the bronchial surfaces to the affected area. The haemorrhage usually stops at once, the method having failed in only six out of a hundred cases. Recurrences may be prevented by repeating injections twelve-hourly for three days, or even six- or eight-hourly should recurrence take place in under twelve hours. Dr. Giuffrida has shown that adrenaline introduced intratracheally has only a local haemostatic action and is without appreciable effect on the blood pressure. The value of the method has been confirmed by Cioffi and Grossi, but does not appear to be as well known as its practical worth would justify. I think the reason for this is that the technique is thought to be complicated and delicate, and its performance to require training and experience. This is not really the case. Although supraglottideal injections may be difficult under normal conditions owing to pharyngeal and laryngeal irritability it is usually easy in the patient with haemoptysis whose psychic condition is associated with a diminution of reflexes.

MAURIZIO ASCOLI,
Director of Department of Internal Medicine, University of Catania.

TREATMENT OF ACTINOMYCOSIS.

IN view of the recent reports of the successful treatment of *actinomycosis* the following account may be of some interest, even although the result was not happy.

A young man, aged 21, was admitted to hospital on May 28th, 1927, complaining of abdominal pain and vomiting of about ten days' duration. There was a cough, accompanied by mucopurulent sputum, and some rigidity on the right side of the abdomen; indeed, for a time the case was closely observed in view of the possibility of appendicitis. However, in a few days the abdominal signs largely disappeared and, with the development of dullness and other signs of consolidation at the right base, a diagnosis of pneumonia was made. The patient was discharged on June 29th, 1927. The general condition was not good, although all physical signs in the chest and abdomen had cleared up.

On August 23rd, 1927, the patient was readmitted as a case of tumour of the pelvis, there being burning pain on the left side of the abdomen of about three weeks' duration. He had not been fit for work since dismissal, but had not been confined to bed. Examination showed the presence of a firm swelling occupying practically the whole of the left iliac region, and extending an inch or two to the right of the middle line; it was subtympanitic to percussion, and tense, but not fluctuant. The affected area was somewhat board-like to the touch. A rectal examination was negative. The condition was thought to be probably a tuberculous abscess in the abdominal wall. Examination of the lungs was negative. By August 25th the patient was running an intermittent temperature. The swelling was now fluctuant, so it was incised; an abscess cavity in the abdominal wall was opened, and a fair quantity of blood-stained "cold" pus evacuated. This was examined microscopically, but the report was indefinite. The induration surrounding the area gradually increased, and a clinical diagnosis of probable actinomycosis was made. Granules were observed in the pus, and these, when examined microscopically, showed streptothrix mycelium. The condition gradually became worse. Sinuses developed in the hypogastric and right iliac regions, some of them discharging faecal material, and death ensued on May 16th, 1928.

Treatment began in 1927 with the administration of intravenous injections of collosol iodine; 1,176 c.cm. were thus given between September 11th and 29th. Thereafter, until October 21st, collosol iodine was given by mouth in doses of 1 oz. three times a day. On October 25th treatment with the French tincture of iodine in milk began, the initial dose being 2 minims twice daily; this was gradually increased up to 7 minims twice daily; it was discontinued about the end of February, 1928. The iodine was well tolerated, but clinically the condition did not improve. X-ray treatment was also employed under competent directions. No vaccine therapy was tried.

ACCIDENTAL TRANSFIXION OF PELVIS BY A METAL STAIR-ROD.

THE following clinical details of an interesting surgical case appear to be worthy of record.

A steelworks labourer, aged 35, was admitted to the Royal Infirmary, Sheffield, on September 28th, 1928, after an accident. While going downstairs he trod on the end of a loose stair-rod, and fell heavily, in a sitting position, on to its upturned end, which penetrated his perineum. He walked a few yards crying for help, and then fell to the floor, being seized with very severe pains down his left thigh.

On admission he was seen to be lying on a stretcher in the knee-elbow position with his knees apart, and though obviously in great pain he was not suffering from any marked degree of shock. About twelve inches of a bent thin brass stair-rod protruded from his perineum. The entrance wound was just to the

right, and in front of the anus, and the buried portion, which was afterwards found to be about ten inches in length, traversed the pelvic cavity; the distal end could be seen sticking up under the skin of the abdominal wall in the left iliac region, as shown in the accompanying reproduction of a photograph which was taken after he had been anaesthetized.

The patient was anaesthetized in the knee-elbow position, prepared for operation, and then turned over into the lithotomy position. After rectal examination and the passage of a full-sized metal catheter had shown that the bowel, urethra, and bladder had escaped injury, the stair-rod was pulled out with some difficulty.

The entrance wound was then excised, and the track of the rod was found to run through the central point of the perineum just posterior to the bulb of the urethra. The patient was then placed on his back, and the distal part of the track was exposed by a curved incision in the left iliac fossa. After division of the muscles of the abdominal wall the intact peritoneum was stripped back, and the contused blood-stained track through the substance of the ilio-psoas muscle was seen to run down into the pelvis, deep to the undamaged external iliac vessels. The peritoneum had escaped injury, as the rod appeared to have passed from the central point of the perineum between the layers of the levator ani muscle to the wall of the pelvis, which it followed closely in its upward course round the brim into the iliac fossa. The peritoneum was not opened, as there was no sign of effusion into it; both wounds were stitched up without drainage; the patient was given 1,000 English units of antitetanic serum and 25 c.cm. of anti-gas-gangrene serum.

On the day after operation it was obvious that the left anterior crural nerve had been injured, as a complete paralysis of the quadriceps extensor group of muscles was associated with anaesthesia of the skin over the anterior and inner aspects of the left thigh. The abdominal wound healed by first intention, while the perineal wound for some days showed signs of mild infection. The limb was put up on a back splint, and treated daily by massage and galvanism, and the man was discharged to out-patients on November 6th with the leg in a walking calliper splint.

I am indebted to Mr. T. B. Mouat, who performed the operation, and to Mr. Finch, under whose care the man was, for permission to publish particulars of his case.

House-Surgeon, Royal Infirmary, Sheffield.

Reports of Societies.

ULTRA-MICROSCOPIC VIRUSES.

RESUMED DISCUSSION AT ROYAL SOCIETY.

THE discussion on ultra-microscopic viruses infecting animals and plants, which was opened at the Royal Society on February 28th (reported in the *British Medical Journal*, March 9th, p. 447), was continued on March 14th, with Sir DAVID PRAIN in the chair.

Vaccinia and Variola Virus.

Professor J. C. G. LEDINGHAM, chief bacteriologist of the Lister Institute, said that his impression, after listening to the first part of the discussion, was that these ultra-microscopic viruses appeared to be similar in most of their characteristics and pathogenic features to visible bacteria, the only difference being one of dimension. Further enlightenment, he thought, would come on the microscopical side through the efforts of Mr. Barnard and his colleagues. Professor Ledingham then passed on to consider the variola virus and the extraordinary transformation after passage through animals, such as the ox and calf, which had made vaccination against small-pox possible. There was a parallel in rabies virus, which, after passage through rabbits, was so altered as to have power no longer to infect dog or man on subcutaneous inoculation, and this had brought into being the Pasteurian antirabic treatment. He did not think that the possibilities of securing living attenuated variants had been quite adequately explored in connexion with animal viruses. It was possible that the immunity conferred by the killed virus was not of long duration; it might be just sufficient to give protection for the period during which the host was susceptible to the disease, but it was not in the same class as the immunity conferred by vaccination against small-pox. With regard to tissue affinity, it had been shown that in the case of certain viruses the point of attack was the reticulo-endothelial system, which took the chief part in the defence. Much which was of general applicability to the study of viruses had been gathered from experiments designed to test how far their proliferation in the tissues could be inhibited or enhanced by the artificial alteration of the "seed-bed" into which they had been introduced. It was known that the action of a virus could be enhanced by adding to it some tissue extracts, or be inhibited by causing some inflammation of the skin—for example, by x rays or the injection of Indian ink. In this respect these viruses did behave very similarly to visible bacteria, and were influenced in the same way. The question of combined virus and bacterial action was also interesting. The classic instance was the association of *B. suipestifer* with the virus of swine fever.

Dr. R. N. SALAMAN, director of the Potato Virus Station, Cambridge, spoke of virus disease as affecting the potato plant. It had been suggested that physiological disturbances due to the introduction of a foreign protoplasm into the plant might be the cause of virus disease, but from experiments, of which he gave an account, he thought it could be concluded that in the potato there was a virus disease which was certainly not due to any physiological disturbance. One curious feature of the potato experiments was that the potatoes of the best varieties were the best carriers. The differences in tolerance were rather striking, and simply from the different degree of the plant's tolerance two varieties of disease could be distinguished one from the other when both produced the same symptoms.

Evolution and the Virus.

Professor F. W. TWORT, superintendent of the Brown Institution, University of London, said that if the ordinary theories of evolution were accepted it must be admitted that the bacterium was a highly organized being, and that there existed forms which were more primitive, otherwise the evolution theory would have to be modified. If there were these more primitive forms in existence it seemed not unreasonable to think that the viruses might be representatives of such forms, and if they existed as viruses in disease it was probable that they existed also outside disease. It would also follow from the supposition that these viruses were representatives of more primitive forms of life, that they must have existed before the organic world was built up, and thus could not have had originally organic material as their foodstuff. They must have obtained their energy from some other source—for example, atmospheric or electrical. It was well known that there were certain atmospheric conditions, particularly those involving electrical disturbance, which had considerable influence on certain states known to be associated with bacteria—for example, decomposition of milk. Climatic conditions also affected materially the appearance and extent of certain effects. Ordinary bacteria, again, would show differences in action according as to whether they were placed in a copper-lined incubator or in a cupboard open to any electrical disturbance that might be present. The speaker suggested that beyond the ordinary radiations which were known to be beneficial or even essential to man—the rays of light and heat—there were other rays of much higher frequency which were detrimental. He had himself carried out a considerable number of experiments on rays of a range of about 31 metres, and he had found indications, particularly with regard to bacteriophage, that these rays had some effect upon the activity of the parasite.

Differences in Immunity.

Dr. C. H. ANDREWES said that the impression left on his mind after the first meeting was that most of the speakers were of opinion that viruses might not be very different from bacteria, and that the immunity might be very much the same in both cases. He wanted, however, to take up the opposite point of view and to stress the differences in immunity as between bacteria and viruses affecting animals. In the first place, most virus diseases left behind them an immunity which was very definite or even absolute—absolute in the sense that it could not be broken down, as the immunity with most bacterial diseases could be broken down, by giving sufficiently large doses to the agent. The immunity was also very lasting, even apparently lifelong. Some workers suspected that this very lasting immunity might be associated with latent persistence of living virus in the animal. Again, it was not possible to immunize in general nor to evoke the production of antibodies against the virus by using heat-killed virus; on the other hand, it was possible to immunize and evoke the production of antibodies by inactivating the virus with such substances as phenol. But this failed to explain the rather remarkable fact that the production of antibodies with these killed viruses could only be effected by using an animal species naturally susceptible to the disease in question. Further, the serum of animals immune to virus disease contained certain antibodies which appeared to be different from other antibodies. In no case had it been shown that the antigen concerned in these reactions was the virus itself. The more characteristic antibodies associated with virus infections had these properties. If an immune serum was mixed with the virus in question and inoculated into a susceptible animal, the typical local or general infection exhibited on giving the virus alone, with no serum, did not develop. It had been assumed that the antibody had acted on or neutralized or perhaps killed the virus *in vitro*, but it did not follow that this obvious explanation was necessarily the correct one. The speaker described some experiments which had shaken his faith in the theory of the union of the virus and antibody in vitro. Further, some experiments at present in progress with vaccinia had indicated also that there was no evidence to be obtained at all readily of any union of the virus and the antibody in the circulation of the animal. If no union occurred outside the body nor in the circulation, one suspected that the essential protective action of the immune serum had to be sought for in the neighbourhood of the cell itself. Yet there were other experiments, again with vaccinia, which suggested that the protective action

of the immune serum did not occur if the virus had been allowed to get inside the cell beforehand. The virus was apparently able to multiply and flourish in the cell which was bathed by fluids containing the antibody. This made one wonder whether the protective action of the immune serum might not operate on the surface of the cell, preventing the virus from getting inside the cell and invading it. He believed there was enough evidence to indicate that the body's defence against a minute parasite such as a virus was probably a very different thing from its mode of protection against the larger bacteria.

Electrical Behaviour of Viruses.

Dr. S. R. DOUGLAS, director of the department of experimental pathology, National Institute for Medical Research, spoke on the electrical behaviour of these viruses. Previous to 1927, observations of the migration of the virus in the electrical field had given most discordant results, but during that year Dr. Todd of the National Institute devised an apparatus for working out these experiments. Using the bacteriophage of the Shiga dysentery bacillus, under different electrical conditions with various *p*H concentrations, the virus was found always to travel to the positive pole. In many of these virus diseases the blood had been found infective. Attempts had been made to discover in what portion of the blood the virus was situated. The history of these researches began with work on rinderpest, when it was found that blood which had been centrifuged and divided into two portions, one consisting of plasma and the other of cells, was free from all virus in the plasma, while the cells were highly infected. In 1914 Charles Todd, again working with rinderpest, found, not only that the plasma was not infective, but that the virus was contained almost entirely in the leucocytes; at least, the leucocytic layer contained one hundred times as much virus as the red cell layer. More recently, Wilson Smith, working in the speaker's laboratory with vaccinia, found that even after intravenous injection of the vaccinia virus into rabbits the plasma was infective for the first twenty-four hours, but that after that, up to the ninth or tenth day, the virus was confined entirely to the leucocytes, the red cells *being free. In the later stages, from the fifth to the ninth* day, although there was a considerable amount of virus present in the leucocytes, the plasma contained a large amount of antibody, which was completely able to mask the production of the lesion when the whole blood was injected.

Yellow Fever Virus.

Dr. EDWARD HINDLE spoke on the yellow fever virus, which, he said, was only moderately filterable. It passed through the coarser filters, and was arrested by the finer ones, but a very peculiar effect emerged from the filtration —namely, that the virus had a different size in the blood from what it had in the mosquito which transmitted the infection. This suggested that some form of evolution took place in the intermediate host. The virus in the mosquito was arrested by even the coarest kinds of filter. Another point which supported the view that the virus of yellow fever was a living organism was the undoubted variation in mortality in virus diseases. In epidemics of yellow fever variations ranging from a mortality of 10 per cent. up to one of 80 or 90 per cent. were found, and the speaker thought that this could be explained by assuming that the virus had similar variations to those found in plants and animals. The features of immunity in most of these animal virus diseases seemed to be distinct from the immunity in bacterial diseases. The very solid immunity obtained in the case of virus disease was a very peculiar thing. In yellow fever the inoculation of a presumably killed virus had produced an immunity in monkeys which, tested up to five and a half months, had shown no sign of diminution, and was continuing.

Dr. BRIERLEY of the Rothamsted Experimental Station said that one of the outstanding differences as between animal viruses and plant viruses was the weight which was placed by the pathologist upon filterability. The plant pathologist did not pay anything like as much attention to filterability as the animal pathologist. A great many plant viruses were not filterable at all, or, if they were, nothing was known about this property. Another striking feature of plant viruses was the way in which they existed in a large number of closely related strains which in nature were yet quite distinct. This had been shown by Dr. Kenneth Smith and others in this country. The extreme specificity of insect transmission in many plant viruses was also very striking. Certain insects would only carry certain viruses. He believed the virus to be some form of organism of the same order of life as bacteria.

Mr. J. E. BARNARD showed a few more slides illustrating the results of his work in ultra-violet microscopy. Among the examples shown were colonies of the virus of bovine pleuro-pneumonia. Photographed by ultra-violet light with dark ground, they appeared well differentiated, whereas in visible light, Mr. Barnard said, it would have been impossible to ascertain from the structure the type of organism. Mr. Barnard said that in his opinion there were at least two saprophytic viruses, probably non-pathogenic, which it was possible to grow and reproduce, though not with great regularity. Of viruses in general, he said that it appeared that these organisms could grow and reproduce themselves in the same way as the ordinary bacillus, but they could also revert to a form in which reproduction was, in his opinion, by an entirely different mechanism.

Is the Virus a Growth-promoting Substance?

Professor A. E. BOYCOTT, director of the pathological department, University College Hospital, who closed the discussion, took up the question of the ultimate origin of the viruses. What had struck him about these viruses was their likeness in behaviour to ordinary pathogenic bacteria. *But wherein did the likeness consist?* In certain superficial resemblances, in the fact that they multiplied (and anything that multiplied we called life), in the fact that they were easily destroyed by heat, which was also known to be destructive of living things, and also in the fact that they caused, like known bacteria, definite disease which could be transmitted from one individual to another. These were, of course, strong reasons—though all of them were on the ground of analogy—for saying that these organisms resembled bacteria. But several of the speakers had evinced a certain uneasiness as to whether these viruses did belong to the same order. There were many considerations which gave rise to doubt. Might not analogy be equally invoked to explain the viruses on the lines of growth-promoting substances? If one took a tissue culture and desired to grow it, one could stimulate it, generally for convenience with embryonic tissue, though it was not necessary that the tissue be embryonic; and by spreading it out, it was possible to grow a great deal more than one started with. In other words, there was a process of multiplication, not essentially different from what was found in, say, the virus of foot-and-mouth disease. This growth-promoting substance, which came into action, for example, immediately following a cut finger, was very similar in some respects to the virus, but no one would say that it was, in any sense of the word, life. The cancer virus differed essentially from the viruses causing epidemic disease, because what it brought about was a local disease belonging to an individual, and there again a form of multiplication occurred very similar to what happened in ordinary growth-promoting substance of normal tissue. With cancer virus, unlike viruses causing epidemic disease, it was possible to start at the beginning, experimentally. In the case of the virus of foot-and-mouth disease, or canine distemper, or measles, it was necessary to start with the disease in question, but in the case of cancer virus one need not necessarily start with *the tumour.* The tumour could be made to begin by irritating the tissues. It seemed to him that with these viruses analogy could be thrown whichever way was desired. It was analogy in either case, and analogy was all that was possible. Take it in one way, and the virus was like a bacillus; take it in another way, and it was more like a growth-promoting substance. At present it seemed impossible to find any criterion which would enable a distinction to be made between them.

TREATMENT OF TETANY.

AT a meeting of the Section of Therapeutics of the Royal Society of Medicine, on March 12th, with the president, Professor J. A. GUNN, in the chair, a preliminary communication on the treatment of chronic tetany with steatorrhoea in adults was presented by Dr. G. C. LINDER and Dr. C. F. HARRIS.

Dr. Linder dealt first with the different types of tetany, and called attention to some of the difficulties encountered in any accurate study of calcium and phosphorus metabolism. He pointed out that the association of tetany and fatty diarrhoea in children with coeliac disease and in adults with sprue had been recognized for many years. This study of three cases of chronic tetany with steatorrhoea in adults, one of whom had suffered from sprue, showed the calcium and phosphorus in the serum to be very much lower than the normal. The tetany was therefore allied chemically to that of rickets. Detailed determinations of the intake and excretion of calcium and phosphorus were made as frequently as possible, as well as observations on the serums, and Dr. Linder showed many charts illustrating the vast amount of work entailed. In the first case calcium chloride by the mouth proved a most effective agent for the relief of tetany and restoration of a normal concentration of calcium in the serum, but after a long period the occurrence of pains in various parts of the body called attention to the fact that decalcification of bone was occurring. This was attributed to neglect of the depression in serum inorganic phosphorus, which was deepened by the acid effect of the calcium salt. Subsequent treatment of this patient with calcium lactate, a high phosphorus diet, and irradiated ergosterol resulted in a positive balance of calcium and phosphorus and a rise of serum phosphorus to normal without fall in serum calcium or recurrence of tetany. The patient soon began to lose her pains, but it was four months before definite evidence of recalcification could be seen in skiagrams. The second patient was treated with radiostol from the beginning, and responded to it in a most satisfactory manner, both the calcium and the phosphorus in the serum becoming normal in two weeks. The beginning of the rise was accompanied by a threefold increase in the excretion of calcium and phosphorus, and this appeared to mean that the vitamin had caused these substances to be withdrawn in large amounts from their depots in the bones, and that the effective threshold for their excretion had been exceeded. This excessive excretion occurred only for the first week, although the level of calcium and phosphorus continued to rise in the serum, and the threshold must therefore have risen too. A fat-poor diet could not be expected to improve on the already satisfactory condition of the patient, but aided considerably in the improvement of her comfort and her state of general nutrition. She increased greatly in weight, the radiostol was discontinued after seven weeks, and no tendency to relapse had been noted in the past four months. The third case was one of sprue, and the patient reacted poorly to radiostol. Although there was some increase in calcium and phosphorus in the serum this was not maintained, and the tetany was unrelieved. The addition to the treatment of a strict fat-free diet was immediately effective in restoring normal serum chemistry and in relieving the tetany. From a consideration of the results of treatment and the metabolic data Dr. Linder formed the opinion that the condition of tetany was due, not to direct interference with the absorption of calcium and phosphorus, but rather to prolonged interference in fat absorption, leading to a deficiency of vitamin D. Treatment directed to the increased supply and better absorption of vitamin D appeared to be more promising than the administration of calcium salts.

Dr. DONALD HUNTER described a case very similar to those reported by Dr. Linder in which ergosterol was given, leading to a rise in the serum calcium and the disappearance of signs of latent tetany. In this form of treatment he thought it had been shown that calcium was drawn from the bones. He mentioned the occurrence of cataract in cases of post-operative tetany, and stated that, with the aid of the slit-lamp, he had found lens opacities present in the case he was investigating.

Dr. GEOFFREY EVANS emphasized the fact that the patients described by Dr. Linder had to be kept on a very strict fat-free diet, and he thought this form of treatment might be of great value in all cases of fatty diarrhoea.

Dr. J. TREVAN inquired if the patients were considered to be suffering primarily from vitamin D deficiency, and whether the decrease in fat intake had been shown to lead to an increase in fat absorption, which seemed to him to be the most remarkable feature of such cases.

The PRESIDENT said that a long time ago he had been puzzled by some of the problems of calcium absorption. He was struck in the present series of cases by the effect of comparatively short periods of administration of ergosterol. He inquired whether Dr. Linder had come to any conclusion as to what calcium salt ought to be included in the *Pharmacopoeia*, and what dosage ought to be recommended. Dr. LINDER replied to some of the points raised in the discussion.

THE FUTURE OF MATERNITY SERVICES.

THE Section of Obstetrics and Gynaecology of the Royal Society of Medicine joined with the Maternity and Child Welfare Group of the Society of Medical Officers of Health, on March 15th, for a discussion on the future of the maternity services. The chair was taken by Dr. J. S. FAIRBAIRN, president of the Section.

A Plea for a Specialist Obstetric Service.

Professor J. MUNRO KERR (Glasgow) recalled the achievements of the last decade, during which great advances had been made in maternal and infant welfare. The supervision of women during pregnancy had definitely lessened the incidence, and still more markedly the severity, of the obscure metabolic disturbances of that period; abnormalities in the position of the child, as well as other complications, could be anticipated, though, unfortunately, the number of women who sought medical advice during pregnancy was not so great as it should be. But the concern of the present discussion was with what Mr. Eardley Holland had called "the tactics of obstetrics," which, still being faulty, resulted in too many casualties. The chief reason was the difficulty of domestic practice. In most medical schools the undergraduate now received proper instruction in obstetrics, yet, even so, he could not leave his school as a perfect obstetrician any more than as a perfect surgeon, although the very day after he was qualified he might, as a locumtenent, be called upon to deal with a placenta praevia or some other serious complication. The public would not agree that such a man should perform a major surgical operation, but there was an idea that parturition was an uncomplicated process, which in very many instances it was not, and even in the simplest case there was a risk of septic infection. Furthermore, a large body of general practitioners did not wish to engage in obstetric practice, for which attitude he did not criticize or blame them, for general practice was as exacting as ever, and required a continually increasing knowledge of medicine. All he asked of general practitioners was that they should allow domestic practice to be so modified as to relieve them of this part of the work which so many found irksome. The reasons why domestic practice could not be satisfactory were:

1. The difficulty in securing surgical cleanliness.
2. The employment of midwives and nurses in domestic duties in addition to attendance on the women.
3. The difficulty of obtaining adequate assistance if operation was necessary.
4. The fact that midwifery practice disturbed the routine of a busy practitioner, so that he was tempted to expedite delivery unnecessarily or prematurely.
5. The fact that 60 to 70 per cent. of obstetric practice in the artisan class had passed into the hands of midwives, so that the general practitioner's opportunities for practice in the craft were limited.

The general practitioner, in his view, should be an expert physician, in close touch with the consultant, the clinical pathologist, and the health officer of the district, but he must no longer be a "jack of all trades." Preventive medicine depended most upon general practitioners, who detected disease in its beginnings, and they should not be worried by obstetric practice, but devote themselves more to pure medicine. It followed that some form of

obstetric service should be established, with a sufficient number of hospital beds to accommodate all primiparae, as well as those multiparae whose labour was likely to be complicated; multiparae in whom uncomplicated deliveries were likely might be attended in their own homes by trained midwives. In Glasgow, to provide beds for all primiparae would mean doubling the total available beds if each patient was to be kept in hospital for ten days; but the speaker thought that many of the women could be taken to hospital by ambulance at the commencement of labour, and after three or four days be similarly taken home without risk. This service, at least in all large centres, should be delegated to obstetric specialists, who would also supervise the work of the midwives, and thus keep them up to the standard inculcated in their training. But even with the best system there would necessarily be an irreducible minimum of casualties; puerperal infection could never be absolutely stamped out.

The Role of the Public Health Officer.

Dr. J. J. BUCHAN (M.O.H., Bradford) was unable to go so far as Professor Munro Kerr in seeing a vista of obstetric specialists conducting routine midwifery practice in this country. Professor Kerr's view of the general practitioner in this branch of medicine ran counter to his own. Dr. Buchan regarded the general practitioner as a potent force in public health—the outlying scout who detected early defects and errors. It would be a calamity from more than one point of view if the general practitioner were divorced from midwifery. The dangers of childbearing were due to three causes, in order of importance: (1) the unfitness of the woman, owing to defects in health or physical development, to undergo the ordeal safely; (2) want of knowledge and failure to seek advice and help on the part of the pregnant woman; and (3) want of facilities for advice and treatment. Maternity work was no longer regarded as the service given by experts from the onset of labour to the end of the lying-in period; the medical profession and the public were slowly becoming conscious of the need of supervision throughout pregnancy, and in the future more attention would be paid in general to the correction of errors in young women which were likely to interfere with normal function. There would be more study of the physiology of the female. The causes of difficult maternity were to be found in very many cases quite early in life, and could be prevented or mitigated long before any question of maternity itself arose. There were, of course, other defects and diseases which appeared later, and were liable to endanger life during child-bearing. How far a woman suffering from nephritis should undertake the risk of maternity was a matter which only the most skilled opinion could determine in each case. To check and prevent such occurrences would seem to demand a procedure of health examination and certification before marriage, an end scarcely likely to be attained within a reasonable time. One practical possibility which might lead to a diminution in maternal mortality was a development of the National Health Insurance Act whereby maternity benefit would be administered, not in cash, but in the form of beds in a maternity service. The midwife, in Dr. Buchan's view, was essentially a health officer; her duties were to observe and supervise the normal. In the care and treatment of abnormalities in any form her duty as an independent practitioner ceased with their detection; her duty then became that of a nurse working under the direction of a medical practitioner. Even the general practitioner should regard his duty primarily as hygienic and preventive. To an increasing extent he was engaged only for abnormal midwifery, with the result that he tended to regard all midwifery as abnormal. Progress in maternity work would be attained by the development of the work of the midwife and the practitioner in preventing physiological abnormality, rather than in seeking the successful treatment of it once it arose. Nevertheless, no scheme could be regarded as efficient in which the fullest use was not made of the obstetric specialist. The ideal would be for the specialist to see every patient in the course of pregnancy and in the early stage of labour. The obstetric specialist must be a real part of the service, linking up the other parts. Unhappily, in all branches of medicine, the really critical diagnosis—the first diagnosis—was often made by the people who were less skilled, in the out-patient department, for example, while the skilled man came later to correct the diagnosis, and perhaps perform the operation.

The Creation of a Maternity Tradition.

Mr. EARDLEY HOLLAND thought that Professor Munro Kerr's views might be realized in the far future; in the meantime one had to depend on the general practitioner and the midwife to do the bulk of maternity work, though institutional midwifery was increasing, and would increase. A criterion of the efficiency of a maternity service was the maternal mortality rate. This rate, obstinately high, indicated that the service was not a good one. Obstetricians understood the reason well enough, but they could not convert to their views the responsible heads of medical thought and education in this country, nor those responsible for public health. The standard of maternity service in any country depended essentially on a tradition, and in this country a great maternity tradition did not exist. This was not the fault of the professional obstetricians, who had been putting up a great fight for years, and had overcome a great deal of opposition. They had persuaded the General Medical Council to impose a certain minimum period which students must spend in the maternity wards; they had secured an increase in the duration of training of midwives from six months to one year; they had caused the institution under the Conjoint Board of a clinical examination in obstetrics and gynaecology; they had brought about the creation of maternity wards in several of the medical schools of London. Public health authorities had also been active during the post-war period. They had issued many eloquent reports, arousing, and even frightening, public opinion; they had established a large number of ante-natal clinics; they had caused important Acts of Parliament to be placed on the statute-book; they had appointed committees to consider various aspects of the question, had instituted inquiries by medical officers of health into all cases of death in childbirth, and had made new regulations for the notification of puerperal pyrexia. That was a fine record, but what had been the result of the activity? The maternal mortality rate refused perversely to diminish. The speaker's criticism of the maternity policy at present pursued by the Ministry was that the Ministry had tackled the problem in the wrong way, and had failed to go to the root. The Ministry had no direct power to reform medical education or to spend large sums of money in building new maternity hospitals and training schools. But the Ministry had not paid enough attention to the views put forward by the obstetricians. The money and man-power at present expended in minor and ineffective measures—ineffective because they did not lower the mortality rate—would give a better return if spent in supporting the reforms urged by the Royal Society of Medicine Committee in 1919 with regard to teaching. The salvation of the position would be large maternity hospitals with attached training schools of university standard staffed by resident experts. If these were established in the right centres the true maternity tradition would be created, first in the medical profession, from which it would spread to the general public. These large hospitals and training schools would not only afford every medical student and midwife an adequate training in midwifery, but they would train the young obstetric expert or specialist, who in this country at present had but small opportunity of receiving training. Mr. Holland went on to urge what he called the three-division principle for all maternity hospitals: a large division for the "clean" cases, a smaller division for emergency cases—cases of ante-partum haemorrhage, and difficult labour of any nature, every one of which was potentially a case of puerperal infection—and, the smallest division of all, for frankly septic cases which arose in hospital. A great deal of puerperal infection in small maternity homes and hospitals was due to the mixing up of the emergency cases in the labour wards and maternity wards with the "clean" cases, cross-infection occurring before the attendants had any warning that a particular case was really infective. The speaker ended with a criticism of ante-natal clinics. The country had "gone mad" on ante-natal work, which had been given an exaggerated importance. He was sure that far more women died from lack of attention during

labour than from lack of care during the ante-natal period. A great deal of ante-natal work, especially municipal, was in his opinion utterly irresponsible, simply because the doctor or person in charge of the patient at the ante-natal clinic during pregnancy was not responsible for her care during labour.

The Position of Midwives.

Dr. EUSTACE HILL (M.O.H., co. Durham) said that his own impression, contrary to what Professor Munro Kerr had suggested, was that the newly qualified practitioner was very keen on taking up midwifery, and this had even led to a certain amount of feeling against the midwife. Professor Kerr's suggestion that midwifery practice should be placed in the hands of expert obstetricians would not be popular among practitioners, at least in many parts of the country. Many obstetric consultants were apt to take too narrow a view of the problem, visualizing it only as applied to large towns, with the provision of maternity hospitals and homes. But in the West Riding, Durham, and Northumberland, to speak only of his own part of the country, there were large areas where it would be impossible, even with motor-car provision, to get any specialist to a case before the need for him was over. He could not agree with Mr. Eardley Holland's criticism of ante-natal clinics. Truly they were in their infancy, many were imperfectly staffed and conducted, and the essential co-operation between the clinic officer and the general practitioner was lacking; but nobody could deny that a proper ante-natal service must be of great value to the community. Large maternity hospitals were desirable, but they would not solve the problem of the urgent case in the remote district. In his own county quite 20 or 25 per cent. of the cases booked for admission to maternity hospitals or homes could not get there before the event was over. In the midwife he was a firm believer, and he was anxious that her status and remuneration should be improved. Her position in scattered districts was one of exceptional difficulty because there were not enough midwifery cases to enable her to make a living. He had looked with anxiety upon the combination of the duties of midwife and ordinary nurse, but he was bound to say that he had found no definite evidence of a tendency to sepsis in midwifery cases attended by a midwife who had been doing nursing duty. The elimination of the handywoman was very important, and one thing which would tell in that direction would be a requirement that every woman eligible for maternity benefit should engage either a properly qualified midwife or a doctor.

Education in Obstetrics.

Lady BARRETT said that probably all obstetricians were convinced that maternity work in hospitals was quite the best type of work done, but she hoped it would not be forgotten that the whole matter was at present in an intermediate stage, and, frankly, she did not think they were quite in a position to define the share to be taken by the general practitioner in obstetric work; at the moment this was very considerable. A few measures might be adopted to enable him to do his work with very much greater facility and satisfaction to himself. She suggested that every patient should have a qualified midwife even though a doctor was in attendance, because it was quite impossible for a busy general practitioner to give the time that the best midwifery required. She could not help thinking that it would be possible to enable these highly trained women to give anaesthetics in the second stage or, at any rate, in the later part when the doctor was present. Although Mr. Holland had spoken in congratulatory terms about the better education of the medical student, yet, even in the schools which gave the longest training, only three months were entirely devoted to midwifery, or six months to midwifery and gynaecology, and the recipient of this training on setting up in practice was supposed to be called in by a midwife who had spent a whole year of training in nothing but midwifery. The standard of education was still decidedly too low.

Dame LOUISE MCILROY thought that the general practitioner ought to conduct the ante-natal examination, and the midwife ought to co-operate with him in the care of the patient. She thought that ante-natal clinics might be run by a panel of general practitioners who had shown interest in and aptitude for midwifery; this would be specially useful in country districts. Mr. Holland had been a little too critical of the public health service. After all, it was only the people responsible for the service, apart from the teachers, who had advanced obstetrics, and obstetricians had until recently stood aloof in questions of administration. Obstetricians were inclined to be unfair in their criticism of the general practitioner; what had they done for his instruction? There were post-certificate classes for midwives, but she was not aware of any post-graduate facilities for the general practitioner, enabling him to take an intensive course. The general standard of teaching ought to be raised; at present the practical teaching was largely given by house-surgeons and juniors in the wards.

Dr. W. S. A. GRIFFITH said that the crux of the problem was the better education of the general practitioner and of the midwife. Within the last twelve months he had read two reports in the *British Medical Journal*, both emanating from Scotland, recounting a series of disasters so terrible that they could only have been the result of a state of ignorance almost inconceivable on the part of those responsible for them. More facilities for teaching were very necessary.

The General Practitioner Defended.

Dr. F. W. H. OXLEY (Poplar) declared that the obstetric specialists of the country were really the general practitioners. Professor Munro Kerr was trying to remove the general practitioner out of practical midwifery. The speaker narrated some of the things which general practitioners had done in this sphere. It was a general practitioner practising in Huddersfield in the later years of the last century who introduced diagnosis by abdominal palpation, and insisted that it was only rarely necessary for the woman to be examined vaginally. It was a general practitioner in the East End of London in the middle eighties who was the first to introduce into this country ante-natal work on a large scale. Another general practitioner, practising in a small country village, was the first to draw the attention of the profession to the very great danger that puerperal fever might be carried through droplet infection from cases of septic industrial accident. While the general practitioners were doing all this, nothing whatever of practical effect was being done by the professional obstetricians, and it required the Chief Medical Officer to the Ministry of Health to wake them up to take an interest in this state of affairs. He thought it only due to a large body of men doing excellent work, often under the most dreadful conditions, to say so much in their defence. On the general question he looked to developments of the maternity service under the National Health Insurance Act. The number of institutional beds needed, he thought, had been exaggerated. Moreover, there was a great danger of infection to healthy patients on going into institutions, so much so that in Aberdeen the death rate in the midwives' cases was only 2 per 1,000, whereas in hospital it was 14 per 1,000; the difference was put down almost entirely to this factor of infection.

Dr. STELLA CHURCHILL, speaking with regard to the domiciliary treatment of midwifery cases, said that she personally would regret very much to see the extension of the Insurance Act to dependants from this point of view so long as the general practitioner had not received an adequate training in midwifery, for the results were not likely to be much better than they were to-day.

Maternity Hospital Administration.

Sir EWEN MACLEAN (President of the British Medical Association) said it was common ground that better facilities were needed for the training of the medical student. Those at present concerned in teaching had gone through many trials and tribulations in order to secure that degree of betterment which did at present exist in the maternity services of the country. There was a tendency to bring railing accusations against the profession as a whole, and it was not appreciated what difficulties a number of them had encountered in their generation over this matter in securing a reasonable number of beds for tuition. It had been stated that the number of additional

beds required for a maternity service to cover the country would be not less than 50,000. But the mere fact of having a maternity hospital, large or small, was not sufficient in itself; a great deal depended upon the way in which the hospital was run and staffed. He was convinced that the ideal method was that in practice at Cardiff at the present moment; there were 51 maternity beds in the Royal Infirmary in direct association with the ante-natal clinics of the local authority. The principal ante-natal clinic, indeed, was situated in a portion of the maternity hospital itself. The association with the general hospital was very advantageous, because its general or special departments were available for service when *required. The speaker believed that the first material con*tribution to a system for dealing with midwifery cases in general would come through the development of the national insurance system, still practically only at its commencement. The proposals made in this connexion by the British Medical Association in its evidence to the Royal Commission were at least worthy of very careful consideration. He was sure that no obstetric specialist had intended his words to express anything inimical to the general practitioner, who was, indeed, the first line of defence, and without whom no ideal system of midwifery service could be reached.

The CHAIRMAN (Dr. Fairbairn) recommended both Dame Louise Mellroy and Dr. Oxley to peruse the *Proceedings* of the old Obstetrical Society and the present Section, from which they would find that nearly all the recent reforms had been foreshadowed by the obstetricians, although, of course, they could do nothing until the authorities took up the matter. He added that he thought there was one unmentioned factor which assisted in the maintenance of maternal mortality. Under the present social conditions the mental attitude of women towards child-bearing had been widely affected. They shrank from what it might involve in the way of pain and suffering, and demanded anaesthetics and a quick termination of labour. The medical attendant at a confinement had pressure brought to bear upon him to this end, not only by the patient herself, but by the husband and friends; such pressure was difficult to resist in a domiciliary case, though easier in a maternity home or hospital.

Professor MUNRO KERR, replying, said that Dr. Oxley, although he claimed the title, was not a general practitioner: he was an obstetric specialist in general practice. Dr. Oxley had asked what contributions obstetricians had made. The speaker would remind him that two of the greatest contributions to practical medicine were made by obstetricians—namely, by Semmelweis, with whom originated the scientific pathology of septicaemia, and by Simpson, who was the first to employ anaesthetics in obstetric practice. Dr. EUSTACE HILL, who also replied, paid a tribute to the general practitioner, the best type of whom, he thought, was found in scattered country districts. The country practitioner was a most able and accomplished man, quite capable of doing much which in the town would be referred to the expert.

CHRONIC METRITIS.

AT a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland on January 25th, with Sir WILLIAM SMYLY (in the absence of the president) in the chair, Dr. D. J. CANNON showed a specimen of chronic metritis.

Dr. Cannon said that chronic metritis, like chronic endometritis, was a relatively rare condition. The majority of cases of so-called chronic metritis were in reality instances of chronic subinvolution, as had been shown by the researches of Goodall and others.

The patient, a nulliparous woman, aged 36, had been operated upon for double prosalpinx about four years previously. On account of the healthy condition of the cervix a Sturmdorf operation was first of all performed, and afterwards both tubes and ovaries had been removed. The uterus was elevated by suturing the round ligaments to its back. As a result of the operation the patient was relieved of all her symptoms except a mucopurulent discharge. About six months before the meeting the patient had returned to Dr. Cannon on account of this discharge, which gave rise to a most annoying eczema and general ill health. She looked anaemic and debilitated. Dr. Cannon performed a complete hysterectomy, and the patient was now restored to health.

The following pathological report had been received on the specimen. "This specimen consists of a small uterus without tubes or ovaries, also a small piece of separate tissue. Sections cut from the small fragment show it to be derived from the cervix. It is composed of fibro-muscular tissue with a partial covering of stratified squamous epithelium. At one point the epithelium is slightly broken, and here there is an area of infiltration with chronic inflammatory cells, plasma cells, and mononuclears. There are a few dilated blood vessels in the body of the section. On cutting into the uterus the mucous lining is somewhat swollen, and the muscular structure shows many small red points. Microscopical sections taken through the wall, including the mucous membrane on both sides of the lumen, show the muscular layer to be in a state of fibrosis and containing many thick-walled blood vessels. The mucous membrane is atrophic, and although glandular acini are present, they are not numerous. There is no evidence of tubercle or malignant disease. The specimen appears to be a fibrotic uterus."

Dr. Cannon said he thought that this case was also interesting from the point of view of the treatment of pelvic infection. As a rule conservative radical treatment, rather than complete hysterectomy, was the treatment of choice. Should there be chronic endocervicitis, some operation should be performed on the cervix as part of the conservative radical treatment. Treatment along these lines helped to cure the discharge in the majority of cases, and this gave clinical support to the view that a vaginal discharge usually had its origin in the cervix, and not in the body of the uterus. Dr. Cannon thought that the pathological report explained the failure of conservative radical treatment in this case.

Sir WILLIAM SMYLY asked if the uterus had shrunk since the tubes had been removed. He did not think that pathologically there was any difference between chronic metritis and fibrosis uteri. Dr. J. S. QUIN referred to the fact that at the time of the second operation the patient's chief symptom was profuse leucorrhoea. This produced symptoms of very great discomfort, and was often very difficult to deal with. He congratulated Dr. Cannon on his success in curing it in this case of hysterectomy, since very often it was not cured by this operation. He asked if the discharge had been bacteriologically examined. Dr. F. W. DOYLE stated that this patient had a tuberculous history, and some years before her marriage had had bone tuberculosis. He had been present at both operations; at the first the case seemed to be one of tuberculous tubes, and on the second occasion there seemed to be a mixed infection.

Dr. CANNON, replying, said that the uterus had shrunk since the removal of the tubes. When he first examined the patient he had suspected tuberculous tubes, but after the operation no tuberculosis had been found. He had not considered radium treatment, since he believed it had been stated that radium should not be used in true cases of chronic metritis where there was a discharge as well as haemorrhage. The discharge, which was muco-purulent, had been examined, but no gonococci had been found.

Sequels of Radium Treatment.

Dr. BETHEL SOLOMONS showed a uterus which he had removed by the Wertheim method from a multipara, aged 57. Regular menstruation had ceased for four years, but a year ago she started to bleed irregularly. On examination there was found a typical squamous cancer of the cervix, which bled easily on examination, and seemed fixed to all the fornices. It was a borderline but somewhat dangerous operative risk. Radium was inserted by Dr. Stevenson, and she was closely watched for four months. Gradually the appearance became nearly normal, but as she had two haemorrhages during that time, he decided to remove the uterus. A microscopical report stated that the glands showed no abnormality; there was no evidence of malignancy, and the muscle walls revealed much hyaline change. There was no excessive fibrous tissue during the operation, but the left ureter was slightly out of its usual position. Recovery was uneventful.

Dr. W. C. STEVENSON, who had given the radium treatment, said that the dose in this case was rather larger than usual, because it had been applied in more than one place. If it had all been given in one site that area would probably have been destroyed altogether. He had begun treatment on October 2nd, and continued it for three days; on the fourth day the patient had taken some bovril, after which severe diarrhoea followed. Dr. Stevenson had used 49 millicuries of radium, and had kept the

radium as far away from the rectum as possible. The cavity of the uterus was 7 cm. long; the radium tube was left for twenty-four hours, and was then pulled down a further two centimetres and left for another twenty-four hours, at which time it was just at the cervix.

Dr. W. A. TAYLOR said that the sequence of events after radium treatment which was described in textbooks had not occurred in this case. The stage of hyperaemia had appeared when the patient had suffered from diarrhoea, but there had apparently been no stage of sloughing, since nothing in the nature of a slough had come away. After the diarrhoea ceased, the condition of the cervix very rapidly improved, and, in fact, it appeared to have healed. This case, he thought, brought to notice the position of radium in the treatment of carcinoma of the cervix at the present time. These cases were classified in the literature as operable, borderline, and non-operable cases. He personally believed that radium removed the borderline cases, since all surgeons now decided to see what radium would do for these patients before operating. The question of giving this patient a further course of radium had been considered, but she had passed from a condition of parametric involvement to one in which no such involvement could be found, and so it appeared that the time for operation had come.

Dr. D. G. MADILL stated that in this case he would have removed the uterus. He thought that a few years ago the dose of radium applied by Dr. Stevenson had been considerably smaller than he now employed. He asked how many needles had been used, where they had been inserted, and whether in some cases needles should be inserted and left in for about six days without being disturbed, as recommended by Dr. Webster.

Dr. A. H. DAVIDSON asked if Dr. Solomons had experienced any difficulty in performing the operation, since it was generally supposed that after radium treatment much fibrous tissue formed and made the Wertheim operation difficult. He thought it possible that the haemorrhages were of fibrotic origin, and wondered whether the radium treatment would not have been sufficient, and whether the operation was necessary and would do good. Radium affected mostly the nearer cancer cells, and not the deeper ones; if in the present case it had killed the more distant cells no operation would have been necessary.

Dr. R. STUMPF said that there were three ways of treating cases like that of Dr. Solomons—namely, radium, deep *x*-ray therapy, or combined treatment by *x* rays and radium. According to recent statistics, the results obtained from each of these were about the same. At a recent meeting of radiologists it had been stated that radiotherapy was as effective in operable cases as was surgical operation. In borderline cases, cure by radiotherapy could be obtained in from about 10 to 15 per cent. Considering that the operative technique in these cases could hardly be improved, and that radiotherapy was only in the early stages, he thought it likely that the time might come when surgical operation would be abolished even in operable cases and all be treated by radium.

Dr. STEVENSON, replying, said that it was sometimes difficult to know how long to wait after radium treatment before operating in these cases. In the present instance, the treatment had been very intense, and the operation had been performed nine and a half weeks afterwards; he thought that this was about the right time to wait. He had not used needles, but had employed the screen method, by which it was possible to supply a much more diffuse dose, and one which was more likely to affect the parametrium. He thought that leaving in the needles for six days would result in giving a very good dose, though he had at present a patient in whom he thought he would leave them for fifteen days.

Anaesthesia in Labour.

Dr. J. S. QUIN read a paper on scopolamine-morphine narcosis in labour; he first described the method used by the Freiburg school and then detailed the method adopted by himself. He considered it important that the first injection should be given to the patient as soon as labour had started, and a further injection after the child was born. In 25 per cent. of the patients treated the result was very good, in 15 per cent. the result was good, and in 10 per cent. there was no apparent benefit from the treatment.

Dr. D. G. MADILL said it had been stated that after the judicious use of scopolamine-morphine the patient would fall asleep, and labour would pass without the patient remembering much, if anything, about it. His experience was that scopolamine-morphine had not been so successful as this. He noticed that Dr. Quin, out of sixty-one cases, only regarded fifteen as complete successes. Dr. Madill attributed failure in some cases to want of complete silence in the patient's surroundings. In his opinion scopolamine-morphine was not the ideal anaesthetic in obstetrics, and he thought there were great possibilities in rectal ether administration.

Dr. BETHEL SOLOMONS said he did not advocate twilight sleep as a general measure; he thought it should certainly be given to the primigravida who dreaded childbirth, and to the multipara who had had a severe time during her first confinement, and who looked forward with fear to the second. There was no doubt that the method was not ideal, and that "blue" babies were often born. The room should never be darkened, for it was necessary that the nurse should have a good view of the patient. Much harm had been done by advocacy of the method in the lay press, and the establishment of twilight sleep homes, where the doctor in charge was not always a specialist in obstetrics. He believed that the ideal anaesthetic in labour had not yet been obtained.

Dr. F. W. DOYLE referred to a gas-oxygen apparatus which had recently been installed at the Coombe Hospital, and said that this method was now being used in America, and, according to the literature, with extremely good results. Gas-oxygen could be given with perfect safety to both mother and child, and did not interfere at all with the progress of labour. It was claimed, indeed, that it accelerated rather than retarded its progress, and it did not cause any interference with lactation.

Dr. A. H. DAVIDSON thought the great disadvantage of scopolamine-morphine narcosis was the supervision which was necessary. It would not be easy for a busy obstetrician to visit a patient every three hours, but if the nurse could be sufficiently trained to give the injection and to see that the patient did not come to any harm from it, it would be a different matter.

Sir WILLIAM SMYLY, referring to the rules laid down for the beginning of scopolamine-morphine injections, thought that the right time to begin the injection was when labour became painful; treatment should be confined to the first stage of labour. Most patients in private practice insisted on receiving some kind of injection, but scopolamine-morphine was certainly not the ideal treatment; it eased patients, however, and helped them greatly in the first stage. Its great drawback was the uncertainty of the result.

THE DIAGNOSIS OF ACHONDROPLASIA.

AT a meeting of the Devon and Exeter Medico-Chirurgical Society at the Royal Devon and Exeter Hospital, on February 28th, with Dr. F. A. ROPER in the chair, Dr. A. L. CROCKFORD showed a girl, aged 1 year 11 months, the subject of achondroplasia. Dr. Crockford said that at first the possibility of thyroid deficiency had been borne in mind, but the mental development and normal articulation in the absence of the natural fullness over the thyroid gland had negatived this alternative diagnosis, made when the infant was aged 6 months. There had been protuberance of the tongue from the earliest days; the typical shaped head, with depressed bridge of the nose, was present, and the lack of parallelism in the fingers resulting in the so-called "trident" hands was of diagnostic significance. An interesting feature of the case was the occurrence of superimposed post-natal rickets, as evidenced by a rickety rosary, and the outward and forward bowing of the femoral bones and tibiae. The treatment employed had been directed to the true (post-natal) rickets, and included cod-liver oil and attention to the diet. Dr. Crockford added that he had been unable to find anything adverse in the family history suggesting a predisposing cause, nor

was there any history of the occurrence of this condition in relatives.

Dr. FAYLE SEALE, commenting on the case, said that achondroplasia and rickets were diametrically opposed from the pathological point of view, in that achondroplasia resulted in premature ossification, while rickets held normal ossification in restraint.

Etiology of Localized Oedema.

Dr. R. N. CRAIG showed a woman, aged 50, who had developed bilateral oedema of the eyelids following an attack of erysipelas. There had been pyrexia during the infective stage of ten days, and then an apparently quiet interval. The swelling of the face recurred, and, in turn, disappeared for four weeks. There had followed the present oedema of the lids, which had remained constant for the past three months. There was considerable swelling below the orbit on each side, and the wearing of spectacles was rendered very difficult on account of the deep pitting set up by their pressure. All protein tests had proved negative. An angioneurotic origin had been considered when the case was first seen. No treatment appeared to benefit the condition, the calcium group of salts being among remedies given a trial.

Dr. W. A. DATE said he had found thyroid extract useful in similar conditions, but Dr. JACKSON thought that the history of infection and the subsequent progress of the case pointed to obstruction of the lymphatics. Mr. NORMAN LOCK mentioned that he had known a similar state of localized oedema to follow a cat-bite.

Treatment of Diabetic Coma.

Dr. F. A. ROPER showed a young man, aged 20, who was just recovering from diabetic coma.

The patient had been admitted to the Royal Devon and Exeter Hospital on February 25th, drowsy, with marked air hunger, patches of cyanosis all over the body, a poor, rapid pulse, and a strong smell of acetone in the breath. He had been under treatment for diabetes for five years, and had been taking 60 units of insulin and following a diet of nine "lines." Two days before admission he had bicycled about twenty-five miles, the temperature on that day being well below freezing point. In the evening he felt ill, and had subsequently had no inclination for food up to the time of admission, but had complained much of thirst. On admission he was noted to be a well-nourished, muscular young man, and to be in a state bordering on coma, with a considerable quantity of urea and acetone in the urine; the blood sugar figure at that time was 0.312. An injection of 30 units of insulin was given at once, and the dose was repeated for three consecutive hours. The same dose was repeated in four hours, followed by 20 units four hours subsequently, until, at 8 p.m. (fifteen hours after admission), a total of 110 units had been injected. At this period the urine was found to be free from glucose. Any attempt at natural feeding was frustated by vomiting at this juncture, and glucose was given by injection only. Since the time of admission there had been several periods when collapse seemed to be imminent, and stimulation had to be effected with brandy, camphor in oil, and digitaline. From midnight up to 3 a.m. on February 26th the progress was more hopeful, but half an hour later the patient was again on the verge of coma. A catheter passed at this time withdrew only 5 oz., the urine being loaded with glucose and acetone. The insulin treatment was renewed energetically, together with glucose injections. At 7.30 a.m. he had sufficiently recovered to take a beaten-up egg and half a pint of milk by the mouth. Improvement was maintained up to 9 p.m. on February 26th, when the patient was found to be sugar-free, but at 1.45 the next morning there was a further relapse, with a return of the glycosuria and acetonuria. At 8 a.m. he showed distinct improvement, 50 units of insulin having been injected during the period of relapse. From this time onward there had been progress, and the cessation of vomiting had permitted a definite diet to be given of 950 calories in the twelve hours, during which 85 units of insulin were administered, the urine remaining sugar-free all the time. When shown to the meeting the patient was conscious, and was practically sugar-free; 20 units of insulin were being given at three-hourly intervals, with 2 drachms of glucose. Feeding ranged from one and a half to two "lines," and had included grape fruit and chicken broth.

Dr. R. A. P. GRAY, who had kept very full notes of the case during the critical periods, gave a detailed account of the three days' continuous combat with coma. He said that success, at any rate temporary, appeared to be probable as a result of the energetic treatment employed. Dr. W. A. DATE, who had attended the patient for some five years, described him as active and athletic, but one who was difficult to maintain on a diet sufficient for his natural requirements. Dr. Date had never known the urine to be entirely free from acetone in this case.

Diagnosis of Still's Disease.

Mr. NORMAN LOCK showed a boy, aged 7, with arthritis of the rheumatoid type. He said that, when first seen early in 1927, there was limitation of movement, and pain, in the left hip. A diagnosis of tuberculosis had been suggested in the first instance, but subsequently the right knee, and later still the left knee, became involved with effusion into, and thickening about, the joints. Treatment had been general, with splinting to prevent deformities, and also three doses of thiosinamine. There had been some slight rise of temperature for nearly two years, but the range was within the normal limits now, and the joints were moving well. Mr. Lock said that, in spite of there being no accompanying splenic enlargement with the arthritis, the true diagnosis was Still's disease.

Dr. T. R. C. WHIPHAM recounted a somewhat similar condition in a boy under his own care several years ago; in this case, however, there had been definite enlargement of the spleen and lymphatic glands. There were several remissions during the observation and treatment, which had been continued for three years. A short-circuiting operation was performed for "colon cut-out." Three weeks after the operation Dr. Whipham had been astonished to find the boy up and about, and able to run down the road. Unfortunately this improvement was only maintained for six months, when the symptoms recurred, and steady deterioration ensued, the boy eventually succumbing to the affection.

ACTION OF LEAD ON THE TISSUES.

AT a pathological meeting of the Liverpool Medical Institution, on February 17th, Dr. M. DATNOW read a paper on the effects of lead on the tissues. After a brief historical review of lead poisoning, Dr. Datnow gave an account of experimental work carried on for the Liverpool Medical Research Organization. The animal employed was the rabbit, and the chief lead preparations used were the phosphate, aspartate, glutamate, hippurate, malate, iodobenzoate, and the benzoyl aspartate, in colloidal suspension containing 0.5 per cent. Pb. The lead colloid was introduced by intravenous injection. Dr. Datnow said that as the liver, with the possible exception of the spleen, was the main organ concerned in taking up lead from the blood stream, it was also the organ which first showed pathological changes. With massive doses, or with very toxic preparations such as 10 c.cm. of lead malate, or 5 c.cm. of the more toxic benzoyl aspartate, extensive haemorrhage was found throughout the liver substance. With therapeutic doses there was only transient cloudy swelling, which cleared up in twenty-four hours. This was confirmed by liver function tests and by clinical observations. Intermediate doses produced extreme dilatation of the capillaries, with compression of the liver cells; the zone of the central vein was first affected. Similar changes were observed in the kidney. In the heart muscle, apart from haemorrhages with lethal doses, no definite pathological changes were found. The spleen showed increased pigment, with dilatation and congestion of the sinuses. Dr. Datnow also briefly mentioned the selective choriotropic effect of lead first pointed out by Blair Bell. He concluded by describing the effects of lead on rat tumours (Flexner rat carcinoma and sarcoma), demonstrating the destruction of the malignant cells, with increased fibrosis in the tumours, after treatment with lead aspartate. The paper was illustrated by a large number of lantern slides.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society, held on March 7th, with the president, Mr. GEOFFREY BATE, in the chair, Sir ROBERT JONES, Bt., gave an address entitled "The problem of fractures," in the course of which he dealt particularly with fractures of the head and neck of the femur, and those at the ankle, wrist, and lower end of the humerus. He paid special attention to practical points in diagnosis, and indicated the best methods of treatment, illustrating his remarks with demonstrations on a living subject. He insisted on the necessity for early reduction of recent fractures, and for patience in after-treatment, giving many valuable hints for dealing with various cases.

Reviews.

FRACTURES.

THE first edition of Dr. KELLOGG SPEED'S *Text-Book of Fractures and Dislocations*[1] showed him to be as competent a teacher as he is a surgeon. The second edition, of which the text has been entirely rewritten, may be considered almost as a new book. In the days before 1914 compound fractures were rare, but mechanically propelled vehicles on the open roads of every country have produced a great increase in the number of cases of compound fractures of the most serious and extensive kinds, very often infected from the first. Tetanus and gas gangrene were rare—at any rate in this country—before the war, but now it is found necessary, or at least prudent, to give injections of antitetanic serum after road accidents, and to be always on the alert for the early stages of gas gangrene. Naturally, therefore, on examining such a book as this we turn our attention first to the chapter on the operative treatment of fractures, in which the treatment of compound fracture is discussed. The advice Dr. Speed gives on this subject is very sound, and should be taken to heart by every surgeon who finds himself in charge of a compound fracture. The main points insisted on are: the desirability of treating all compound fractures as if they were infected; débridement, or, as the author prefers to call it, épluchage of the wound, including, of course, the skin edge and projecting bone; the need for avoiding or exercising great care in the use of tourniquets; and the value of drenching of the part with an accepted antiseptic solution.

The paragraph headed "What not to do for open fracture" is equally important. "No attempts at reduction, removal of foreign material, picking at the wound, sticking instruments or fingers into the wound, should be made in the first aid." This rule needs emphasis, particularly in the instruction of Red Cross and St. John detachments, for the ardent amateur is much more likely than the practitioner to be led away by his wish to "do something." For shock no alcohol is to be used. The best first-aid treatment of this condition is by warmth, recumbency, and morphine. The author's remarks on the indications for primary amputation are very sound. In the account of the technique of épluchage we find no reference to bipp as used by its inventor, Rutherford Morison.

As for skeletal or direct traction, Dr. Speed gives the following warnings limiting its application: the nail or wire or tongs must not (early) pass through the haematoma of the fracture, the epiphyseal plane, or a joint; it must not split the bone or pass just under the periosteum, where it will cause pain; no foreign material, such as plates, screws, or nails, should be put on the wounds of open fractures. These "don'ts" are of great value, and we quote them to show the author's clarity of expression and the practical nature of his advice. In a very interesting and full discussion of recurrent dislocation of the shoulder and its treatment we find no mention of the important paper by Mr. A. S. Blundell Bankart which appeared in our columns on December 15th, 1923 (p. 1132). It is not evident what method of treatment the author prefers. In the illustrations of flexion treatment of supracondylar fracture of the humerus in the young we think that the angle of flexion is dangerously acute, and must increase the risk of that terror of the fracture surgeon—Volkmann's ischaemic contracture. On this last subject we think that Dr. Speed's estimate of the success of operative treatment is optimistic. Those too often permanently disabling conditions, the fractures of Colles and of Pott, and other fractures near the wrist and ankle, are fully dealt with. The abduction treatment of fracture of the neck of the femur is well described. Needless to say, the necessity for *x*-ray pictures in the treatment of fractures and their medico-legal importance are insisted on, although there are not many radiograms in the book itself.

[1] *A Text-Book of Fractures and Dislocations.* By S. B. Kellogg Speed, M.D., F.A.C.S. Second edition, enlarged and thoroughly revised. London: H. Kimpton. 1928. (6 × 9½, pp. xiv + 952; 927 figures. 50s. net.)

DISEASES OF METABOLISM.

PROFESSOR FREIDRICH UMBER of Berlin is well known in Central Europe as an authority on nutritional and metabolic disorders. His new book on metabolic disorders[2] is a compact and readable synopsis, designed for practitioners, of his well-known larger work on disorders of nutrition and metabolism, of which the third edition, with lengthy post-war revision, appeared in 1925. It resembles in style and scope the Modern Medical Monographs of this country, but is not so well produced as these volumes. Good diagrams are lacking, and there is no readily available bibliography. The book opens with an account of the present state of our knowledge relating to nutrition and metabolism. Detailed reference is made to the large-scale experiments in nutrition made necessary in Central Europe by the war. The known vitamins, A to E, are fully described, with special reference to their action in states of undernutrition. There is a chapter devoted to obesity and its pathology, particular emphasis being laid on the part played by the endocrine system in the production of this disorder; the treatment is described in well-condensed tables. About half the book is devoted to diabetes mellitus. A very well-arranged and complete survey of the etiology, pathology, clinical aspects, and complications is given, and treatment is fully considered. There are further chapters on diabetes insipidus, gout, calculus formation, and metabolic anomalies. The book, which consists mainly of a collection of articles that appeared last year in the *Münchener medizinische Wochenschrift*, contains nothing hitherto inaccessible to English and American readers. But if only on account of the author's great reputation in Central Europe it should be read by those requiring a knowledge of Continental practice in diseases of metabolism.

NEPHRITIS.

ONE of the advantages of endowed lectures at the Royal Colleges is that they stimulate the publication of original work, clinical experience, and reviews of special subjects, and thus may pave the way for a more expanded treatment of the subject. Last year Dr. IZOD BENNETT, a former student of Bright's Hospital, as the Goulstonian lecturer at the Royal College of Physicians of London, took as his subject some problems of nephritis, and now he has in *Nephritis: Its Problems and Treatment*[3] republished these three lectures with but little change, and supplemented them by two fresh chapters on the classification of nephritis and on its treatment. The problem how to fit all the forms of renal disease with their transitions into a satisfactory table has attracted the keen minds of several generations. Dr. Izod Bennett, after criticizing Widal's classification, adopted by MacLean, of hydraemic and azotaemic nephritis as unsatisfactory in that some, and perhaps the majority, of the cases met with in practice fail to fall clearly into either group, brings forward a different classification which is in full accord with Aschoff's recent writings. It consists of three categories: the nephroses; the acute and chronic diffuse, and the focal and embolic forms of glomerulo-nephritis; and arteriolo-sclerosis, divided into the pre-nephritic stage of essential hypertension, the later stage of chronic interstitial nephritis, and the malignant renal sclerosis of Fahr. The chapter on treatment of different forms contains a number of useful tables on diet, and, like the rest of the book, is clearly written and stimulating.

In his compact book *On Nephritis*[4] Dr. CECIL ALPORT has succeeded in giving a clear summary of the present state of medical opinion on the different forms of kidney disease without entering into minute details which might confuse

[3] *Nephritis: Its Problems and Treatment.* By T. Izod Bennett, M.D.Lond., F.R.C.P. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Demy 8vo, pp. viii + 92; 3 figures. 6s. net.)

[4] *On Nephritis (for the Student and the Practitioner).* By A. Cecil Alport, M.D., M.R.C.P. With an introduction by Professor Frederick Langmead, M.D., F.R.C.P. London: W. Heinemann (Medical Books) Ltd. 1929. (Cr. 8vo, pp. xvi + 175; 2 plates, 4 figures, 3 charts. 7s. 6d. net.)

the student and busy practitioner. Dutifully dedicated to "Ricardus Bright, the Father of the Medical Unit System," of whom two portraits are included, the volume begins with a brief historical outline of the subject. Here the probable neglect of the etiological importance of the toxic factor in chronic parenchymatous nephritis is mentioned and illustrated. The author recognizes that his classification of diseases of the kidney into four groups—inflammatory or parenchymatous, vascular, a special group for Rose Bradford's kidneys, and the nephroses—is not absolutely watertight, for the last two cannot be detached from the later stages of the first group, and the senile kidney, though included under the vascular category, is not so much a disease as a part of old age. The several forms of nephritis are then described, and special chapters are devoted to the eye changes in nephritis, to uraemia, and to the urinary and functional tests. An appendix contains "A pharmacopoeia of drugs for use in renal disease (for students)"; this tactful parenthesis may, however, be neglected by the practitioner, who, as elsewhere in this readable handbook, will find much to satisfy his thirst for information and guidance.

SPEECH DISORDERS.

THERE are two comparatively recent works published in the United States that are of value in the consideration of disorders of speech, one by Dr. J. S. GREENE on *The Cause and Cure of Speech Disorders*,[5] and the other by Dr. J. M. FLETCHER on *The Problem of Stuttering*.[6]

Dr. Greene's book is a systematic study, and aims at being a textbook. He differentiates between the person who stutters or hesitates in his speech, the stammerer who is unable to utter certain sounds, and the person whose voice is abnormal. In his view the plight of the stutterer has not been bettered in recent years owing to the continued search for a physical cause of the condition. It is not realized that what he needs primarily is a mental reconstruction besides correction of his objective faulty speech habit and mannerisms. Dr. Greene maintains that there is nothing physically wrong with the sufferer, that he can use his speech organs as well as anyone else, and that time and energy are wasted in physical exercises. Each case demands special treatment, since stuttering is only a symptom displayed by an individual with a nervous constitution. To effect a cure a composite therapy—medical, psychological, re-educational, and social—is necessary. This scheme, it is claimed, has been a great success in the National Hospital for Speech Disorders in New York (the first hospital of the sort), of which Dr. Greene is the director. Stammering, he maintains, is a defect in enunciation which is not dependent upon the emotional speech life of the individual, but upon the mechanical speech life. His treatment, which is set out in full, differs according to the type of defect, and it is claimed that it is most successful.

Dr. Fletcher is a psychologist and approaches the problem from that standpoint and not that of a medical practitioner. He has some scathing criticisms to make of Dr. Greene's methods and of his book; indeed, he charges him with being ignorant of the history of the subject that he is treating! Dr. Fletcher certainly knows his history, and his book is worth reading if only for its summary of what has been done in the past. The number of cures is amazing, from mental to surgical, including a number of operations upon the tongue and throat. There is an excellent review of the most recent work in psycho-analysis. The followers of Freud do not appear to have succeeded. In eleven years Brill handled 600 cases, and attempted psycho-analysis in sixty-nine; five were cured, but one of these relapsed. Reed says that the stutterer will eventually be found to contradict almost every theory that may be set forth regarding the nature of his trouble. He could trace no definite traumatic experiences, no inhibitions against obscene words, and no connexion with sex experience, such as earlier investigators had found. Dr. Fletcher gives a very lucid exposition of his own views. He considers that in these cases we are not concerned with the abstracted processes of articulation with which the speech specialist deals, but speech as a complex mental reaction to a concrete social situation; it is always *ad hoc*. "The situation is a function of vocal communication." This explains the failure of many forms of environmental training. Children in some schools are brought into apparent speech control, but they fail hopelessly so soon as they are outside, for the situation has changed. He maintains that the chief problem in the stutterer's self mastery is that of discovering and of fostering within himself certain mental and emotional states which are (*a*) known to affect his speech favourably, and (*b*) which he finds it possible to maintain under the stress of actual speaking conditions. This book by Dr. Fletcher is a clear and scientific study of a difficult problem.

[5] *The Cause and Cure of Speech Disorders*. By James Sonnett Greene, M.D., and Emilie J. Wells, B.A. New York: The Macmillan Company. (Demy 8vo, pp. x + 458; illustrated. 20s. net.)

[6] *The Problem of Stuttering*. By John Madison Fletcher, Ph.D. London and New York: Longmans, Green and Co., Ltd. (5½ × 8, pp. xiv + 362; 5 illustrations. 10s. 6d. net.)

MELLOR'S CHEMISTRY.

THE eighth volume of Mellor's Chemistry[7] is devoted to nitrogen and phosphorus. Reviews of preceding volumes of this treatise have appeared from time to time in this *Journal*, and little need be added to the praise already accorded to the author's work. It is a classical production in the truest sense, for it is impossible to glance through its pages without gaining the impression that nothing has been overlooked in its preparation. The voluminous references to bibliography appended to each discussion can only be described as amazing. The statements contained in the text are assembled in a connected sequence that must have cost untold labour in arrangement, and, having regard to their multitude, one can only wonder how it was done. Not a word is wasted to make a sentence brief, nor spared to make a sense clear. But the supreme delight is the spirit of romance with which the whole work is clothed, beginning with the dedication which is inscribed: "To the privates in the great army of workers in chemistry. Their names have been forgotten. Their work remains"—and continuing throughout with every attention to the arresting details of history. Thus we may read here how in 1680 Robert Boyle deposited with the secretary of the Royal Society a sealed packet containing an account of his preparation of phosphorus which was published posthumously in 1693, and how Dulong, after his discovery of the dangerously explosive nitrogen chloride, continued his work on this compound after it had cost him the loss of three fingers and one eye. To this book belongs the place of honour in any chemical library.

The ninth volume is also now ready and deals with the group arsenic, antimony, bismuth, and the related rarer elements. In this group there are perhaps fewer matters of general or non-technical interest, and the volume is mainly occupied with the terms of pure chemistry, but there is much information of absorbing interest on arsenic in its relation to life and living creatures.

NOTES ON BOOKS.

THE publication of a sixth edition of *Diseases of Infants and Children*,[8] by Dr. H. D. CHAPIN and Dr. L. T. ROYSTER, within a few years of the fifth is a proof of the popularity of this work. Much revision and elaboration has been necessary to incorporate recent progress in paediatrics, and this has been accomplished without materially adding to the size of the book, although the method of putting a great deal of matter in small print is open to objections. This book is intended essentially for those who wish to have a somewhat complex subject presented in as brief a form as possible. The authors have succeeded in the main, although the result is by no means a small volume, while in places clarity has been sacrificed to brevity. It is to be regretted that no references to authors quoted are given anywhere in the book.

[7] *A Comprehensive Treatise on Inorganic and Theoretical Chemistry*. By J. W. Mellor, D.Sc., F.R.S. Vols. viii and ix. London: Longmans, Green and Co., Ltd. 1928. (Roy. 8vo, vol. i, pp. x + 1110; 156 figures; vol. ii, pp. xi + 867; illustrated, each volume 63s. net.)

[8] *Diseases of Infants and Children*. By Henry Dwight Chapin, M.D., and Lawrence Thomas Royster, M.D. Sixth, revised edition. London: Bailliere, Tindall and Cox. 1928. (6 × 9¼, pp. xv + 675; 184 figures, 9 plates. 30s. net.)

Dr. F. ROQUES's work on epidemic encephalitis in pregnancy, labour, and the puerperium,[9] which represents an amplification of a review recently published in the *Journal of Obstetrics and Gynaecology of the British Empire*, is based on the study of 40 previously unpublished English cases under treatment at Sheffield, the National Hospital, Queen Square, and the Middlesex Hospital, and 171 cases, mostly of Continental origin, collected from the literature. The obstetrical aspect of acute epidemic encephalitis and Parkinsonism, which has hitherto received little attention from British writers, is fully discussed in all its bearings, including the condition of the child born to the infected mother. A full bibliography is appended, but there is no index. The work should find a wide circle of readers, appealing as it does alike to the obstetrician, the neurologist, the consulting physician, and the general practitioner.

We have received three instalments of a new German series entitled practical differential diagnosis for practitioners and students,[10] and edited by Professor GEORG HONIGMANN. They constitute parts 5 to 7 of the first volume, which is devoted to internal medicine. Diseases of the liver and bile ducts are dealt with by Professor GLÄSSNER, medical diseases of the locomotor system by Dr. ERNST FREUND and Dr. ALBERT SIMO, and infectious diseases by Dr. ALBERT HERZ. The information given is concise, clear, and practical, so that these three little works can be consulted with profit by those familiar with the German language.

In a little book entitled *Morpheus, or the Future of Sleep*,[11] Professor FRASER-HARRIS deals in a pleasant and informative way with the subject of sleep. He attributes sleep to four influences—chemical (fatigue products), the absence of sensations, the absence of emotion and ideas, and the diminution of the blood supply of the brain. He gives some hints as to the hygiene of sleep, and discusses dreams, attributing them chiefly to aberrant sensory impressions, and scarcely at all to unconscious influences, as some would do. Finally, he puts in a strong plea for the abolition of noise in the future regulation and planning of cities.

Who's Who in the Nursing World[12] for 1929—the second year of issue—gives information about the various administrative, examining, and training bodies and institutions, and other organizations concerned with the nursing profession, together with biographical notes of its leading members.

Sir RONALD ROSS's Nobel Prize Lecture, originally given in 1902, when the award was made to him, and published under the title *Researches in Malaria* two years later, has now been published in a French translation.[13]

We have now received the second part of the fourth edition of Professor HERBERT ASSMANN's textbook of radiological diagnosis[14]; the first part was noticed in these columns on December 8th, 1928 (p. 1042). The second volume begins abruptly in the middle of the section relating to the stomach, and deals with the remainder of the abdominal organs, the nervous system, and the joints and muscles. Many of the numerous illustrations are good. The book may be recommended as a companion to the first volume, from which it is inseparable owing to the rather unfortunate division of the matter contained in the two parts.

Dr. JOHN D. GIMLETTE's *Malay Poisons and Charm Cures*[15] has now been republished in a third edition, the text having been revised, with numerous additions. This work has been found of considerable practical value to those engaged in medico-legal work in the Far East since it was first published in 1915. It is also of interest to those who make a study of folklore and oriental beliefs and customs. A review of the second edition appeared in our issue of February 10th, 1923.

In *An Investigation of the Milk Yield of Dairy Cows*[16] Mr. J. F. TOCHER, D.Sc., of the University of Aberdeen, gives a statistical analysis of the data of the Scottish Milk Records Association for a number of years. This monograph, reprinted from *Biometrika*, is not only of considerable interest to statisticians, but should prove of practical value to those concerned with milk production.

[9] *Epidemic Encephalitis in Association with Pregnancy, Labour, and the Puerperium.* By F. Roques, M.D., M.Chir.Cantab., F.R.C.S.Eng. Manchester: Sherratt and Hughes. 1928. (Demy 8vo, pp. vii + 143. 15s. net.)

[10] *Praktische Differentialdiagnostik für Ärzte und Studierende.* Herausgegeben von Professor Dr. Georg Honigmann. Band I: Innere Medizin, Teil 5: Erkrankungen der Leber und Galle. Von Dr. Karl Glässner; Teil 6: Innere Krankheiten des Bewegungsapparates. Von Dr. Ernst Freund und Dr. Albert Simo; Teil 7: Infektionskrankheiten. Von Dr. Albert Herz. Dresden und Leipzig: T. Steinkopff. 1929. (Med. 8vo, Teil 5, pp. 327–392, M.4.50; Teil 6, pp. 393–448, 14 figures, M.4.50; Teil 7, pp. 449–552, M.6.)

[11] *Morpheus, or the Future of Sleep.* By Professor D. F. Fraser-Harris, M.D., D.Sc., F.R.S.E. To-day and To-morrow Series. London: Kegan Paul, Trench, Trübner and Co., Ltd.; New York: E. P. Dutton. 1928. (Feap. 8vo, pp. 94. 2s. 6d.)

[12] *Who's Who in the Nursing World.* Compiled and edited by H. E. Smithers. Second year. London: Professional Publications, Ltd. 1929. (Feap. 8vo, pp. xv + 331; illustrated. 5s. net.)

[14] *Die Klinische Röntgendiagnostik der Inneren Erkrankungen.* Von Dr. Herbert Assmann. Vierte umgearbeitete und vermehrte Auflage. II Hälfte. Leipzig: F. C. W. Vogel. 1929. (7½ × 10½, pp. 513–1071; 568 figures, 5 plates. M.35.)

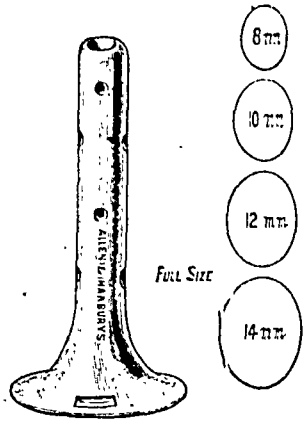
[15] *Malay Poisons and Charm Cures.* By John D. Gimlette, M.R.C.S., L.R.C.P. Third edition. London: J. and A. Churchill. 1929. (Demy 8vo, pp. xiv + 301; illustrated. 10s 6d.)

[16] *An Investigation of the Milk Yield of Dairy Cows.* By J. F. Tocher, D.Sc., F.I.C. From *Biometrika*, vol. xxb, Part 2, September, 1928. London: Biometric Laboratory, University College. 1928. (Imp. 8vo, pp. 165–234; illustrated.)

PREPARATIONS AND APPLIANCES.

DYSMENORRHOEA TUBES OR UTERINE STEMS.

MR. W. MCKIM H. MCCULLAGH (London, W.1) writes: Dilatation of the cervix for dysmenorrhoea gives freedom from pain of the spasmodic type for only twelve to fourteen months, as a rule. Stems have been used to ensure prolonged dilatation at the time of operation, and are inserted for four to five days. Their employment lengthens the time of freedom from recurrence of the pain.



Since those in use are usually of solid glass, and so prevent drainage of the uterine cavity, and also because their measurements are not graduated to suit different sizes of uteri, it was thought that the nest of stems pictured in the diagram would be an improvement. They are silver electro-plated on brass, and of four sizes, 8, 10, 12, and 14 mm., corresponding to the dimensions of Hegar's dilators. They are hollow, and rounded at the upper end; the wall of the tube is perforated with small holes. The base has two apertures for the insertion of a withdrawal tape. They are long enough to occupy the uterine cavity, and so straighten an acute anteflexion of the corpus uteri.

The cervix and body of the uterus are dilated to the extent desired, and a stem of the size smaller is inserted after steadying and exposing the cervical canal by vulsellae on the anterior and posterior lips.

A nest of four of these is made and supplied by Allen and Hanburys Ltd., Wigmore Street, W.1.

QUINOXYL.

Quinoxyl, a preparation recently put on the market by Messrs. Burroughs Wellcome and Co., is a mixture of 80 per cent. iodohydroxyquinoline sulphonic acid ($C_9H_4O_4NIS$) with 20 per cent. sodium bicarbonate. Oxyiodoquinoline sulphonic acid was introduced many years ago as a wound disinfectant under the name "loretin"; moreover, the drug yatren, which has been extensively advertised as a wound disinfectant and also as a gut disinfectant, contains, according to Anselmino, 8-oxy-7-iodoquinoline sulphonic acid mixed with 20 per cent. sodium bicarbonate.

In 1921 oxyiodoquinoline sulphonic acid was recommended as a treatment for amoebic dysentery, and it has been found very satisfactory for this purpose. The dose by mouth is 0.25 to 1 gram. It can also be used as an enema, 5 grams in 200 c.cm. water. The toxic effect of the drug is said to be negligible.

SPRAY FOR LARYNGEAL TUBERCULOSIS.

Dr. PERCY MOREY (Southampton) writes: Those of us who are engaged in dealing with cases of pulmonary tuberculosis have often noticed how very rapidly the cases go downhill once the larynx becomes involved, and how very little can be done to arrest this very troublesome and distressing complaint. From time to time I have tried numerous remedies, chiefly in the form of sprays and inhalations, and have never found anything of real value until recently I tried the effect of a spray of a 2 per cent. solution of collosol mercurochrome (Crookes). This spray is used two or three times a day, with the patient inhaling during the process of spraying, and so far, during the time that I have used it, some three months, every case has benefited—pain has been alleviated, the voice has improved, and there has been a marked improvement in the general condition. Most of my cases have been treated under sanatorium conditions, but, even so, the results from the use of this preparation have been much better than those obtained by any of the other methods I have tried.

British Medical Journal.

SATURDAY, MARCH 23RD, 1929.

THE ULTRA-MICROSCOPIC VIRUSES.

ALTHOUGH the meeting held recently at the Royal Society to consider the ultra-microscopic viruses[1] achieved little in the way of a discussion, it has at least served a useful purpose. It has provided an excellent summary of the present position of our knowledge of these agents of disease which will be appreciated by those of us who are not familiar with the recent developments in this subject, and, what is equally important, it brought together plant and animal pathologists, who were thus given an opportunity—unfortunately a rare event—of exchanging ideas and seeing how this problem is being tackled in a field of work other than their own particular one.

The problem of the nature of these ultra-microscopic viruses is most perplexing, and extremely difficult of solution. It cannot be dismissed as a question of mere academic importance, an attitude that the pragmatist adopts too readily towards much research, for since the work of Beijerinck on the filterability of the agent of mosaic disease in plants, and of Loeffler and Frosch (1898) on the virus of foot-and-mouth disease, the list of diseases, both of plants and animals, which are due to agents of this class has reached such proportions as to make it imperative to understand the nature of these agents and so be in a position to deal with their ravages in a scientific and more successful manner. In man such diseases as small-pox, chicken-pox, zoster, measles, mumps, yellow fever, dengue, and possibly influenza, epidemic encephalitis, and the common cold, are believed to be due to these so-called ultra-microscopic or filterable viruses; in animals we have foot-and-mouth disease, distemper, rabies, fowl plague, swine plague, and rinderpest—an incomplete but formidable list.

What is the probable nature of these viruses? Broadly speaking, there are two hypotheses current. The one would have us look upon them as something unorganized, enzyme-like in nature, possibly the result of some deranged function of tissue cells, which, once having been generated, would be capable of again setting in train those changes which in the first instance produced them. In other words, they are the products of damaged cells, and though capable of engendering disease are more truly the result of it. The other hypothesis envisages these disease agents as living things and quite possibly bacterial in nature. The former view has been ably championed by Boycott, and its supporters have advanced experimental evidence which purports to show that a virus disease can be produced in a healthy animal or plant by the inoculation of virus-free material. Experiments of this kind discount the possibility that stock which appear perfectly healthy can be virus carriers. That such a possibility does nevertheless exist is now beyond doubt, and the evidence which Dr. Salaman placed before the meeting recently is convincing testimony on this point. He described experiments showing how practically every plant of a certain variety of potato, though apparently healthy, carried the virus of a disease which could be brought to light by grafting on to potato plants of a susceptible variety. There is, however, nothing revolutionary in the idea that apparently healthy stock should be virus carriers. It occurs in the case of bacteria, and the work of Webster in America on the carriage of *B. lepiscpticum* (the cause of snuffles) in laboratory stocks of rabbits, and the investigations of Lauda showing that certain stocks of rats are carriers of a bacterium (one of the *Bartonellae*), are excellent examples of this. The latter is of particular interest. This organism can produce an anaemia which is frequently fatal, but the rats never sicken spontaneously; only when the spleen is removed and the balance between host and parasite is upset does this bacterium gain the upper hand and produce disease. Were it not for the fact that this organism can be demonstrated by bacteriological methods this condition might have been cited as an example of the spontaneous production of a virus.

The second hypothesis—namely, that filterable viruses are organized living things—was subscribed to by the majority of the speakers at the Royal Society symposium. Undoubtedly it is difficult to draw a clear line of demarcation between the living and the non-living. There is no single criterion of life, but several features taken together—such as capability of multiplication, adaptability to changes in environment, and the power of assimilation from the surrounding medium without loss of identity—are characteristic of living things. There is much evidence that filterable viruses fulfil these criteria just as much as bacteria do. These viruses, as Sir Charles Martin pointed out, differ only from bacteria in their smaller size and the difficulty of growing them in a lifeless medium. But even these are not features which clearly differentiate. There are visible pathogenic bacteria, such as the leprosy bacillus, which have so far resisted all attempts to cultivate them. Some cultivable and visible bacteria, such as those isolated by Olitsky and Gates from the nasopharynx of man, are filterable, and there is evidence that some of the so-called ultra-microscopic viruses are probably within the limits of microscopic vision. Paschen of Hamburg and Gordon in this country claim to have demonstrated the virus of vaccinia in stained preparations, and Professor Ledingham, from his own observations, said that he saw no difficulty in accepting these bodies as the virus.

While paying testimony to the valuable work which had been achieved by Mr. Barnard in ultra-microscopy, Professor Ledingham expressed the view that there was still much that could be done in the study of the morphology of these viruses by ordinary microscopical methods. Dr. C. H. Andrewes claimed that a distinguishing feature between filterable viruses and bacteria was the type of immunity which they evoked. He stated that infection with a virus gave rise to a lasting (frequently lifelong) immunity, and suggested that this was due to the persistence of the virus in the infected animal after recovery. But there are bacterial diseases, such as syphilis, in which the immunity is determined by the persistence of the infective agent in the body, and as far as the duration of immunity is concerned examples can be cited of virus diseases, such as foot-and-mouth disease, in which the immunity produced is of comparatively short duration, and herpes in man, where practically no immunity at all results from an attack. Further, the immunity which a virus confers varies much with the animal species infected. It is true that Dr. Andrewes cited experiments which suggested that antiviral serums behaved in a different way from antibacterial serums; but the antigen-antibody reactions studied in the past have been characterized by a fundamental similarity,

[1] The first part of the discussion was reported in the *British Medical Journal* of March 9th (p. 447), and a report of the second part is published this week at page 559.

whether the antigen was a simple protein or a living organism. Since filterable viruses are antigenic, and therefore protein, there seems no good reason for supposing that their behaviour will differ materially from that of other antigens and antibodies.

SILICOSIS AND THE WORKMEN'S COMPENSATION ACT.

PROGRESS is being made in bringing under the Workmen's Compensation Act the disabling condition of silicosis, or silicosis accompanied by tuberculosis. Serious practical difficulties led the Committee on *Compensation for Industrial Diseases* (which reported in 1907) to recommend, as the then more prudent course, that the question of scheduling the disease should be kept in abeyance for the time being. In 1917 pressure was again brought to bear on the Home Office to deal with the subject, owing to the successful measures adopted in the gold-mining industry of South Africa, under successive Miners' Phthisis Acts. These measures have greatly reduced illness by watering, etc., to minimize the dust, and by periodic medical examination to eliminate men found to be suffering from the disease, while awarding them generous compensation. As a result a method was devised for dealing with the difficulties of the situation in this country by "schemes," each applicable to a particular industry or group of industries.

At present three schemes are in operation—the Refractories Industries Scheme, the Metal Grinding Scheme, the Various Industries Scheme—while a fourth has recently been issued in draft for the sandstone industry. Perusal of the four schemes brings out what appears to be a strange inconsistency: those for the Refractories and Sandstone Industries embrace compensation for partial incapacity as well as for death and total incapacity, while the other two are restricted to death and total disability. The reason, of course, is mainly the burden placed on an industry by the payment of claims continued over a period of years in cases of partial disability, involving a levy perhaps of 5 or 6 per cent. on the wages bill from the employers in the particular industry. But, further, in these schemes a profound difference is to be observed in the way in which compensation is obtainable by the workman. Thus, *in the two schemes with compensation* for partial incapacity this is obtainable only through certification by a medical board, while in the other two compensation is obtainable through certification by the factory surgeon, with the usual right of appeal, either by the employer or workman, to a medical referee. Now the unsuitability of the certifying factory surgeon for diagnosing cases that involve claims for silicosis is self-evident. It is not that he would not be right in most cases, but that he would never be sure that he was, since he has to make his diagnosis at a single interview (at a fee of 5s.) without the aid of an *x*-ray photograph. *The Various Industries Scheme, which* has just come into force, adopts the discredited rule of restricting compensation to death and total incapacity, whereas the draft Sandstone Industries Scheme, of a later date, handsomely expresses readiness to recognize partial incapacity as rightly entitling to compensation. To be fair one ought to say that the Home Secretary is evidently aware of the Gilbertian quandary, and the appointment of the Silicosis (Medical Arrangements) Committee is a gallant effort at extrication.

Yet another scheme is in preparation—that for the Pottery Industry. The preliminary survey[1] by Drs. C. L. Sutherland and S. Bryson—members of the medical board appointed under the Refractories Industries Scheme—brought out the fact that of 72 elderly men exposed to unmixed flint dust 47 were found with fibrosis, and of 49 of those examined radiologically 23 showed silicosis. We have before us a similar survey by the same highly qualified medical men[2] (working under the supervision of Dr. E. L. Middleton, H.M. Medical Inspector of Factories) of their clinical examinations of 461 men (of whom 231 were radiologically examined) working on sandstone. In this inquiry the examinations were confined to men employed at the time, no cases of persons already disabled being included, but relatively higher proportions were included of those who had worked for longer periods. The disturbing fact emerges that among masons, quarrymen, and wallstone dressers, about 50 per cent. showed positive evidence of silicosis radiologically. The critical period appears to be between twenty and thirty years of employment. A concluding statement in the latest report by Drs. Sutherland and Bryson is important as pointing to real prevention of the trouble by bringing an influence to bear external to the workman—that is, one over which he can exercise no control—namely, a very effective "device for the application of localized exhaust draught for removal of dust produced by pneumatic surfacing tools." This obviously means that a method has been discovered for utilizing for this purpose the compressed air after it has done its boring work.

Public announcement has been made within the last few days of an international conference of experts on silicosis to be held at Johannesburg in August next year, the Transvaal Chamber of Mines contributing £2,000 towards the expenses and the International Labour Office being asked to vote another £1,000. This is all to the good, and should at least (1) throw light on the detailed administration necessary to work out effectively the schemes we have referred to, and (2) induce Continental countries to deal with this problem, the importance of which they have not apparently hitherto realized. As we go to press we see that a Silicosis Committee has just published a detailed account of the occurrence of this disease in New York City,[3] which we hope to discuss in a future issue.

ACTINOTHERAPY.

WE have on various occasions felt obliged to introduce a note of discord into the harmony that has prevailed between the general public, certain over-zealous practitioners, and the manufacturers of arc lamps, on the subject of the therapeutic value of ultra-violet radiation. In this imperfect world no remedy is perfect, and not even the best advertising can make it so. We have endeavoured to indicate some of the limitations of a treatment which many have regarded as a panacea, and to point to dangers that might follow its improper application, without, however, minimizing the real benefits obtainable in suitable cases from its use by adequately trained persons. In this matter we were under the impression that we reflected the views shared by cautious experienced clinicians and workers engaged in academic research. We may recall that on October 13th, 1928 (p. 661), when commenting on papers in the same issue by Professor W. E. Dixon and Dr. C. E. Heald, read at the Annual Meeting of the British Medical

Association at Cardiff, we held that "although actinotherapy cannot fulfil all the claims made for it by some of its more sanguine exponents, there exists a definite set of conditions in which its employment is indicated; and though in skilled hands it may provide a treatment of the first importance, improperly used it may do the gravest mischief. . . . Actinotherapy, properly applied, is an important agent in the amelioration of rickets and surgical tuberculosis—often, indeed, in these conditions producing complete cure; and certain neurological conditions, anaemias, and skin diseases, though not cured, are usually benefited by this treatment." We emphasized, on the other hand, that "to patients suffering from pulmonary tuberculosis, arterio-sclerosis, chronic nephritis, quiescent appendicitis, and various forms of neurosis, the application of ultra-violet radiation may do definite and irretrievable harm." On December 22nd, 1928 (p. 1150), we returned to the subject in an annotation dealing with a dangerous propaganda conducted in certain quarters in favour of *self-administration of ultra-violet radiation by lay persons*. It will be observed that we were content merely to sound a note of warning. The Medical Research Council has now gone much further, and the current belief is that it is bent on putting out the lights with a douche of cold water. In its report for the year 1927-28, to which detailed reference is made elsewhere (p. 566), the Council states that "the use of artificial light to supply only what the right food can give is merely wasteful"; that in the treatment of children "no objective evidence is provided that results have been achieved that could not have been far more cheaply gained by proper food"; that the increased bactericidal power of the blood, shown in the laboratory to be produced by this treatment, "has not yet been correlated with any permanent effects of value in the body"; that the "same effects for good or evil follow inflammation of the skin blood vessels inflicted by heat or by other irritants than light"; and that "there is no present reason to know that artificial light can do more in this way than a mustard plaster." These conclusions are apparently based, in part at least, upon two investigations—one already published, conducted in 1925 by Dr. Helen Mackay under the auspices of the British Medical Association, on the effects of ultra-violet light given by the mercury vapour lamp upon the health of infants from the East End of London (all subnormal in physique), and the other, now in the press, carried out by Dr. Dora Colebrook, with the approval of the Board of Education, on the effects of light upon children at school. The value of such controlled investigations cannot be overestimated; but when, as in this case, they point to conclusions at variance with those of a large body of experienced clinicians and laboratory workers, caution suggests that final judgement should be suspended until a great deal more work has been done and the seeming contradictions in the results have been resolved. The antidote to over-credulousness is not complete incredulity, but a balanced opinion based on full consideration of all the available facts. We are therefore in cordial agreement with the Medical Research Council when, at the end of this section of its report, it urges the need for "properly controlled trials" at hospitals and clinics employing artificial light.

MUSSELS AND MUSSEL-BORNE DISEASE.

IT is a far cry from gaol fever to an oyster-borne or mussel-borne disease, though it is not so very long since the conditions were first actually distinguished. To-day typhoid and typhus are known to be separate clinical entities, yet we can understand how the confusion that once existed between them arose and persisted. Suppose, however, that during the time the conditions remained undifferentiated both a louse-borne and a mollusc-borne origin had been established in respect of the same symptom group, would this etiological differentiation have raised the question of the identity of the clinical complex? The existence of an apparently twofold etiology would certainly have stimulated inquiry, and no doubt a distinction would have emerged in terms of the measures necessary for the control of each of the causative factors. But, however unrelated they may appear, the work of the clinician and the etiologist go hand in hand, and the Ministry of Agriculture and Fisheries was wise to entrust an inquiry into the sources and methods of prevention of mussel pollution to a medical man who may bring to his investigation the informed vision essential to its successful outcome. The report on mussel purification[1] prepared by Dr. R. W. Dodgson is devoted to a detailed account of the part played by the mussel in the dissemination of typhoid fever, and to a discussion of the theoretical conditions and the practical measures involved in the control of this vehicle of infection. In a prefatory statement Dr. E. S. Russell, Director of Fisheries, writes: "It may seem strange that in a fisheries report so much attention is directed to questions of public health. But it is clear that in the long run the interests of the fishermen and of the public are identical. It is not to the advantage of the fishermen to put on the market a food which is or may be a potential danger to the public health, and it is the duty of the Fisheries Department to co-operate with the health authorities in stopping this gap in the nation's defences against infectious disease." This is excellent doctrine. In Dr. Dodgson's report the medical officer of health, and the estuarial and coastal health authorities desiring a concise account of mussel diseases and of the methods adapted to their prevention, will find the material they require. Mussel poisoning includes at least three distinct pathological conditions or types of conditions. The first is "musseling," a toxic idiopathy of which the chief characteristic is an erythematous rash produced in certain susceptible persons in response to the ingestion of mussel protein. The second is a paralytic condition, always grave and at times fatal. This type of poisoning is wholly distinct from "musseling," and has nothing in common with it either in respect of its etiology or of its characteristic symptoms. The cause, indeed, is unknown, but all the cases on record have followed the ingestion of mussels from foul or stagnant waters. The condition is extremely rare, only about ten cases being on record, and probably it could be eliminated altogether if elementary precautions were exercised and only purified mussels eaten. The third variety is a condition of bacterial food poisoning. If purified mussels only were eaten the risk of food poisoning would probably be no greater than that which might follow the consumption of other foods. But the chief problem is undoubtedly in relation to the mussel as an agent in the dissemination of typhoid fever, and Dr. Dodgson's investigations would appear to have rendered possible a method of mussel cultivation by which this particular danger has been successfully eliminated. Potentially, mussels are more dangerous than oysters, not only because their habitat is nearer to sources of pollution, but because they are more liable to be polluted than oysters living under exactly the same conditions. The technique of mussel cleansing does not appear to be formidable, and it is given in detail in the report: in essence it consists of hosing and bedding in sterile baths, by which the mussel is afforded the opportunity of self-cleansing under conditions in which reinfection from its own integuments and accreta is rendered impossible. In order fully to safeguard the public the process should be applied universally, all mussels, whether cultivated at home or imported, being regarded as contaminated. There can be no doubt that these measures,

[1] *Report on Mussel Purification.* By R. W. Dodgson, M.D., M.R.C.P.Lond., M.R.C.S.Eng. Ministry of Agriculture and Fisheries: Fishery Investigations, Series II, Vol. X, No. 1, 1928. London: H.M. Stationery Office. 1928. (Imp. 8vo, pp. xvi + 497; 15 plates, 9 figures, 3 maps. £1 1s. net.)

though they may appear to be unduly rigorous, are economically sound: outbreaks of typhoid fever cost far more than the measures which might have prevented them.

ACCIDENTAL HAEMORRHAGE AND PLACENTAL INFARCTION.

THE etiology of accidental haemorrhage has for some years attracted investigators, who have been primarily concerned with the problem whether toxaemia of pregnancy should be looked upon as the cause of accidental haemorrhage or as its sequel. In 1926 F. J. Browne communicated the results of his experimental studies to a meeting of the Edinburgh Obstetrical Society, and this admittedly preliminary statement was published that year in the *British Medical Journal* (April 17th, p. 683). Professor Browne has continued this line of research, and some further experimental observations have now been published by him in association with Dr. Gladys H. Dodds, in the *Journal of Obstetrics and Gynaecology of the British Empire* (vol. 35, No. 4). It may be recalled that the investigation began in 1923 with the discovery that injecting a rabbit on the twentieth day of pregnancy with *B. pyocyaneus* gave rise to revealed and concealed haemorrhage four hours later, while the kidneys showed the presence of acute nephritis. Repeated attempts during the next two years to reproduce such experimental bleeding failed. Evidence from hospital and private patients began to accumulate, and supported the view that *chronic nephritis existing before pregnancy predisposed to* haemorrhage. In the present investigation, which was undertaken to clear up certain doubtful points, and especially to ascertain the important factors in the production of haemorrhage, a new series of 35 rabbits was injected with sodium oxalate in order to produce chronic nephritis; the rabbits were then mated. At the twentieth day of pregnancy (corresponding to the sixth month in the human subject) acute exacerbation of the nephritis was caused by *a fresh injection of sodium oxalate, after which an emulsion of B. pyocyaneus* was injected intravenously; accidental haemorrhage ensued in every case. The sodium oxalate was excluded as the cause of the haemorrhage by injecting uranium nitrate first and the bacillary emulsion subsequently. It was then found that in the presence of chronic nephritis haemorrhage could be readily induced by the injection of *B. pyocyaneus* alone, without it being necessary to inject uranium on the twentieth day, and that in animals *suffering from chronic nephritis the production of the acute* form by the injection of uranium was sufficient to cause haemorrhage without any subsequent injection of the bacillus. In the absence of chronic nephritis the injection of *B. pyocyaneus* did not usually set up ante-partum haemorrhage, even though the organisms caused acute nephritis, and no external bleeding occurred in any one of ten experiments designed to test this point. Further, the injection of uranium nitrate to cause an acute nephritis was not usually sufficient to induce ante-partum haemorrhage in the absence of chronic nephritis. Though in such chronic nephritic animals albumin may be absent between pregnancies and during the early part of pregnancy, it appears in the urine in the latter half of the pregnancy and before the onset of spontaneous haemorrhage. This is obviously of importance when considering the recurring toxaemia of pregnancy. The authors claim, therefore, that their results indicate that ante-partum haemorrhage is not due to organisms. It seems to be caused either by failure of the kidney to excrete poisons which eventually lead to the haemorrhage when they have accumulated in the circulation in sufficient concentration, or by chronic nephritis interfering with a normal metabolic function of the kidney. The outstanding conclusion of these careful and exhaustive experimental studies is that chronic nephritis is the one important predisposing cause of accidental haemorrhage. The authors discuss at length the pathology of placental infarction and its relation to external and concealed haemorrhage, chronic nephritis being the essential factor in both. They trace also a fundamental similarity between the haemorrhage and infarction found in cases of chronic nephritis and causing early abortion, and the concealed or revealed haemorrhage and infarction occurring in the last three months of pregnancy, and usually styled accidental haemorrhage.

THE EDUCATION OF THE CRIPPLED CHILD.

THE treatment and education of the cripple with the object of making him a self-reliant member of society is now so much a matter of course that it came almost as a surprise to hear, from the historical survey of crippledom given by Sir Henry Gauvain to the Medical Officers of Schools Association on March 15th, how recent is this outlook upon the physically defective. Throughout the centuries the cripple has been the object of pity, though often, among the coarser-minded, of derision, and even Charles Dickens, in his sympathetic delineations, could only suggest a cheery philosophy in acceptance of a hard lot. Dickens's *Christmas Carol*, however, had an outcome which its author could not have foreseen, for it inspired Sir William Treloar in his work for cripples, and ultimately led him to make the Alton experiment. One great pioneer step was the foundation, thirty years ago, of the Mary Ward (Mrs. Humphry Ward) School, now in Tavistock Place, better known as the *Passmore Edwards Settlement, for children* whose physical defects made it impossible for them to go to an ordinary school. This is the school, adjacent to the home of the British Medical Association, which was unexpectedly visited by Their Majesties when opening the Association headquarters in 1925. It was the first school for invalid and defective children to be supported out of the public rates. The first residential cripples' school to receive official recognition was one animated by the same spirit, and in which the medical profession has always taken a deep interest—the Heritage Craft School, at Chailey in Sussex, founded and conducted by Mrs. Kimmins. The establishment of Lord Mayor Treloar's Cripples' Home at Alton was an outstanding result of this new development of the social conscience. Among other aspects of the same movement enumerated by Sir Henry Gauvain was the establishment of open-air schools, the first of which came into existence at Plumstead in 1907. The efforts made to restore crippled soldiers during and after the war also directed attention to crippledom in the civil population, and to the fact that much of it was unnecessary and avoidable; it began to be realized that treatment combined with education was not only an act of pity to unfortunate individuals, but a remunerative proposition for the State. Various investigations were made into the causes of crippling, which are chiefly tuberculosis, infantile and other forms of paralysis, congenital defects, rickets, and accidents. Rheumatism, said Sir Henry Gauvain, crippling enough in later life, rarely produced joint disease and crippling among children. The education of the cripple, suited to his limitations, and directed (especially later on) to a craft at which he might earn his livelihood, had had a distinct therapeutic value. It had brought to the cripple as many of the amenities and advantages of school life as possible. It had stimulated him to catch up with the normal. It had kept him busy, interested, and happy, and helped to remove his sense of inferiority, though there were still some forty hospitals in this country receiving cripples at which educational facilities were not provided. After a tribute to voluntary work, in which all social advance had originated, no step being taken by officialism until it had been tested by voluntary experiment, Sir Henry Gauvain recounted some interesting and highly encouraging cases which had come within his experience at Alton.

DEATH CERTIFICATION AND PREMATURE BURIAL.

THE Births and Deaths Registration Act, 1926, came into force on July 1st, 1927. It will be remembered that it dealt with the registration of stillbirths, and prescribed a new procedure with regard to the certification of deaths and the disposal of bodies. This new procedure has, we believe, operated quite successfully during the past year and a half, the only actual hitch in its smooth working having been overcome by a semi-official recognition by the Registrar-General that a medical practitioner must in certain circumstances be allowed to send the death certificate to the local registrar by the agency of the person liable to act as informant of the death for registration purposes, a course which might be held to be strictly illegal. There is still a serious gap in the law relating to the preservation of infant life left by the definition of stillbirth embodied in the Act, and an attempt to bridge this gap is being made in the Preservation of Infant Life Bill now before Parliament. As regards death certification and the disposal of bodies, however, most reasonable people are satisfied that the Act does, in fact, effect such reforms as were necessary to prevent premature interment or the detection of crime. Nevertheless there still remains a body of apprehensive and dissatisfied persons clamouring for further enactments. It is not unnatural that Sir George Greenwood should be their spokesman in a publication issued by the Oxford University Press on behalf of the Society for the Prevention of Premature Burial, and entitled *The Law of Death Certification*.[1] It consists very largely of a statement of the provisions of the Act of 1926, with comments thereon. The mistake is made of regarding this Act as a Government measure, whereas it was in fact introduced and piloted through Parliament by private members, and therefore could not contain any clause imposing a charge on public funds. There is a great deal of quite unnecessary repetition and reiteration throughout the volume, and a large amount of sarcastic abuse of everyone who does not agree with the writer. Considerable space is also occupied by quotations, mostly some years old, of remarks made from time to time by certain coroners whose taste for notoriety is itself notorious. The main grievances proclaimed appear to be two—one major and one minor. The minor grievance is that, though the prescribed form of the medical certificate of the cause of death may now be signed only by a registered medical practitioner "in medical attendance during the deceased's last illness," there is no definition of what constitutes such medical attendance. It has been suggested that this should mean "personal attendance by the person certifying upon at least two occasions, one of which should be within eight days of death," but Sir George Greenwood wants something more stringent even than this. Actual experience of ordinary medical practice makes it evident that any such definition would be likely to be both inconvenient and futile. The major grievance is that the law still leaves open the possibility of premature burial, inasmuch as it does not require the body to be viewed after death in every case by the practitioner certifying or some other registered medical practitioner. There are, of course, arguments in favour of such a requirement, and there would be no serious medical opposition to it under proper conditions; but its enactment would entail considerable expense either to the State or to the individual, would necessitate the making of special arrangements for the cases in which considerable distances have to be travelled or for action in time of widespread epidemics, and would probably be resented by the public in a great many cases. The opponents of this requirement hold that these considerations far outweigh any advantages that it would have over the precautions imposed by the recent Act. On the other hand, Sir George Greenwood and his fellow reformers cry: "Good God! if there is a chance of one man or woman in a thousand, in two thousand, in twenty thousand, in a million—if there is any possible chance at all—the risk is so unspeakably horrible that such chance ought to be eliminated absolutely and for ever." The "chance" is that of premature burial; and it will be noted that, however small this may be, absolute elimination is demanded. But these reformers keep on reiterating that "there is but one really trustworthy proof that death has occurred in any given instance—namely, the presence of a manifest sign of commencing decomposition." It follows that the compulsory viewing of a body by a medical practitioner must continue in each case until such decomposition is actually evident, and that only on certification that this has occurred can burial or cremation be allowed. Nothing short of this can satisfy Sir George Greenwood's requirements, but it is probable that the general common sense of the public will rest secure with the really adequate protection which the law now affords.

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY.

IN our issue of October 27th, 1928 (p. 760), we announced that, under the patronage of the King, the fifth International Congress of Military Medicine and Pharmacy would be held this year from May 6th to 11th at the British Medical Association's House in Tavistock Square. Previous conferences were held in Brussels in 1921, in Rome in 1923, in Paris in 1925, and in Warsaw in 1927. At the forthcoming congress will be discussed the evacuation of the sick and wounded by water and by air, together with the function of the medical services in combined operations; tropical fevers of short duration; wounds of blood vessels and their sequels; the physical and chemical analysis of glass and rubber articles employed by the medical services; and the standard of dental and physical fitness in the various military services. At the exhibition of surgical appliances, instruments, drugs, and of equipment used by the medical officers of the Army, Navy, and Air Force, to be held in connexion with the conference, will be demonstrated a device whereby medical officers may be enabled to ascertain the degree, and, within limits, the cause of the unfitness of candidates for the Air Force. All members of the British Medical Association in the metropolitan area are cordially invited to attend the exhibition.

INFLUENZA.

IN the week ending March 9th there was a slight decrease in the number of deaths attributed to influenza in the great towns of England and Wales: the total fell from 2,193 to 2,127. In the Midlands and Yorkshire the rate of mortality was still increasing, but in other parts of England the maximum had been passed. The notifications of pneumonia tell the same story. To judge from the rates of mortality and morbidity (from pneumonia), the West Midland area—particularly Birmingham—has suffered more severely in the present recrudescence than any other part of England. In the week ending March 9th the notification rate of pneumonia per 100,000 reached 302.7 in the West Midland area, double the rate in London in the week of maximum (151.4) and much greater than the maximum for the North-Western area (206.1). The rate in Yorkshire is intermediate between that of the Midlands and the North-West, but may not yet be at a maximum. In the North the rate is declining and in the week of maximum was nearly the same as in the worst week of the North-West. It would seem that a decline has begun, although several weeks are likely to pass before mortality is normal.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT.

I.

Each year the report of the Medical Research Council contains so much material that it becomes increasingly difficult to continue the practice of giving an outline of some of the most important aspects of the work carried out under its direction. The report for the year 1927-28 is actually a little larger than last year's, and while no startling new discovery is described within its covers it is a record of steady progress in many branches of research. The sum of £138,000 was provided by Parliament during the financial year, and it is very satisfactory to note that important additions to the available resources have again been made this year by the generosity of private benefactors and various public bodies. Of the total expenditure, the costs of office administration and scientific organization, including travelling expenses for members and officers of the Council, have not exceeded 6 per cent., despite the fact that no free services are supplied by the Post Office, H.M. Stationery Office, or Office of Works. Co-operation with research organization throughout the Empire, referred to in last year's report, has this year been largely attained. In the autumn of 1927, at the request of the Government of India, the secretary of the Medical Research Council, Sir Walter Fletcher, visited India on leave for five months. While there, he served as chairman of a committee appointed to report upon the organization of medical research in India.[1] This committee did very valuable work, and was able to attend the triennial Congress of the Far Eastern Association of Tropical Medicine, held in Calcutta in December, 1927. The secretary was also able to visit other centres in India, and was especially interested in the possibility of interchange of workers with such organizations as the Indian Research Fund Association. Another circumstance which has aided the progress of Empire co-operation was the visit during the last two summers of Professor Lyle Cummins to South Africa at the invitation of the Tuberculosis Research Committee of the South African Institute for Medical Research, and comparison between the methods and results of inquiries in the two countries has afforded important help to the Tuberculosis Committee, both here and in South Africa.

GENERAL SUMMARY OF RESULTS.

An indication of the Council's general policy is afforded by a study of those matters specially selected for mention and discussion in the introduction to the report. This year the Council indicates the steps whereby the treatment of pernicious anæmia by liver and liver extract was investigated at the National Institute at Hampstead, following the reports of American work, and how the co-operation of manufacturing firms was obtained for getting an adequate supply of liver extract for extensive clinical trials. The Council reported upon these investigations, and supplies of the extract were then made available through the ordinary commercial channels by the firms interested. On the subject of treatment by artificial light the report observes that large sums of public and private money are being expended on the provision of artificial sources of ultra-violet radiation while there is no scientific reason to suppose that the treatment of rickets is better effected by ultra-violet rays falling on the skin than by the direct provision of the necessary food values. In fact, states the Council, "it commonly costs three or four shillings to give by light an effective supply of vitamin D that would cost less than a penny if given by the mouth in the form of cod-liver oil or otherwise." Artificial sunlight is used for the treatment of various conditions other than rickets, but careful control work seems to indicate that results are largely negative. During the winter months 1927-28 Dr. Dora Colebrook, in conjunction with the medical officer of health for Willesden, Dr. Buchan, and with the approval of the Board of Education, carried out a scientifically controlled trial of the effects of light upon children at school. A report on these results is now in the press. It appears that the results of the light treatment were wholly negative. There was no greater gain in weight, height, mentality, or "spirits" in the children who received light treatment, and they actually suffered a greater incidence of minor ailments than the rest. There is likely to be a great deal of discussion about this section of the report, and further study seems to be necessary before passing final judgement. Nevertheless, in the opinion of the Council, many of the claims for phototherapy are fantastic, and "it seems fair to suspect that in much of the present advocacy of light treatment the results *post hoc* are accepted as *propter hoc*."

On the subject of radium and cancer the introduction reviews the progress since 1920, when the Council was entrusted by the Government with 2½ grams of radium. "It is not too much to say that the outlook has been quite transformed in that time." It is true that progress has taken place more at some centres than at others, but everywhere there has been improvement in methods, especially in working out the radio-surgical technique of access. It is maintained that for cancer of the cervix and for certain types of cancer of the tongue radium treatment is as efficient as the knife, without entailing nearly the same risk and suffering. Radium treatment in many centres has still to win its way from the inoperable to the operable types of cancer, but the Council believes that the present policy of using every centre both for treatment and research will eventually lead to the evolution of sound methods of treatment. Finally, the introduction refers to the forthcoming publication of a "System of Bacteriology" in nine volumes.

WORK AT HAMPSTEAD.

Thanks to a bequest made to the Council by the late Right Hon. Lord Justice Ronan, K.C., of Dublin, which defrays the whole of the expense, it has been possible to extend the building of the National Institute for Medical Research, and the new annexe, to be known as the Ronan Building, is to be ready for occupation in the spring; Dr. H. H. Dale has been appointed director-in-chief of the institute. In the department of biochemistry and pharmacology work has been specially directed to the subject of histamine and allied substances, and the work has been extended to the study of an unstable choline ester obtained from the spleen of certain animals. Dr. Rosenheim and Mr. T. A. Webster have continued their investigations into the production of vitamin D by the irradiation of ergosterol, and so far have been unable to produce the vitamin by treatment of other sterols or allied substances. In the pathological section the chief work has again been a study of diseases due to filter-passing "viruses." Captain Douglas and Dr. Wilson Smith have studied generalized vaccinia in rabbits, and Dr. Perdrau has made a special study of vaccinia, dealing with the particular form of encephalomyelitis which has on occasions been found in association with vaccinia. His observations reinforce the view that post-vaccinal encephalitis is not directly due to the vaccinia virus, but that on rare occasions in certain individuals the vaccinia may enable an unknown factor, perhaps another virus, to produce the encephalitis. Mr. I. A. Galloway has continued to work at Hampstead on behalf of the Foot-and-Mouth Disease Committee of the Ministry of Agriculture, and various problems in the immunology of foot-and-mouth disease have been studied. Mr. Dobell has continued his study of the intestinal protozoa of monkeys, and his work upon *Entamœba histolytica* has been extended so that various stages in its life-history have now been described for the first time. It has been found that one part of emetine in five million parts of culture medium will kill the organism in certain experiments. In the department of applied optics the work of the past year has been mostly concentrated on technical problems arising in the study of filterable viruses, and the results now obtained by using ultra-violet light constitute a definite advance. In association with Professor Topley of the London School of Hygiene, photographic observations have been made of the "bacteriophage." Mr. T. C. Angus, in the section of applied physiology, has continued his investigations on the sources of ultra-violet rays. He worked out the dosage and superintended the installation of the lamps used at Willesden in Dr. Colebrook's experiments. Dr. Leonard Hill has been continuing his work on

[1] See *British Medical Journal*, December 1st, 1928, p. 1001.

the blood pressure in the capillaries, especially those of the liver, and has concluded that about half the systolic pressure in the arteries is spent in maintaining the velocity of blood flow. With Captain Douglas and Dr. Wilson Smith, Dr. Hill has investigated the effect on droplet infection of spraying a room with antiseptic solutions, and it is concluded that the use of such sprays in public rooms is justified.

BIOLOGICAL STANDARDS.

Since the Therapeutic Substances Act came into force in August, 1927, there has been much work of an expert and advisory kind for the Standards Department of the National Institute. A systematic survey of the different scheduled substances already on sale in this country under licence has been initiated. This year has also seen the completion of the preparation and testing of the standard tuberculin, which has been adjusted in strength to the closest possible identity with the standard originally created by Ehrlich at Frankfort. The Standards Department has also been able to devote some time to substances not yet scheduled. For example, the difficulties involved in the standardization of scarlatina antitoxin have been to a certain extent elucidated by the work of Dr. Hartley. So far he has been able to measure, with some accuracy, the lethal dose of the toxin for the rabbit, and the practical application of his work to the standardization of antitoxin seems to be in sight. Again, an international standard for digitalis has existed for some time, and in response to a demand from British manufacturers the department is preparing an accurately assayed mixture which will be available to such British manufacturers as require it, in advance of legal control. Work in the production of standard cultures and serums has continued, and the demand for these has been maintained. In view of certain criticisms of the Widal test, Dr. Gardner has investigated the problems which have arisen in connexion with this reaction in persons who have been inoculated against typhoid fever, and specially sensitized suspensions of organisms are now available for use in these cases. An epidemic of infectious jaundice among school children in Oxford has been investigated, and while it was negative as far as finding the *Leptospira icterohaemorrhagiae* was concerned, it revealed that 50 per cent. of the local rats were harbouring this organism.

EXPERIMENTAL MEDICINE.

Work in various clinical units throughout the country has been supported by the Council, mostly by the provision of part-time workers. At University College, under the direction of Sir Thomas Lewis, observations on the peripheral circulation have been continued, and Dr. Harris and Dr. Marvin have brought forward conclusive evidence for the first time that the minute vessels of the skin in the mammal are under the direct control of the sympathetic nervous system. Observations upon itching have also been made, and it is concluded that this symptom is due to stimulation of the sensory nerve endings by histamine or its equivalent. Drs. Grant, Wood, and Jones have investigated the irregularities present on the valves of the heart in relation to the infection which occurs in subacute bacterial endocarditis. They suggest that irregularities of surface play a much less important part than the formation of small platelet thrombi. At St. Thomas's Hospital the work of the medical unit under Professor Hugh MacLean has been mostly concerned with various aspects of the physiology of digestion. The generally accepted theory of regurgitation of alkaline intestinal contents into the stomach has been shown to be no longer tenable, and it has been demonstrated that the stomach possesses a self-regulating mechanism for acid. It has also been shown that the secretion of pepsin bears little relation to the amount of acid present in the stomach. Drs. Gardiner-Hill and Forest Smith have continued their work on the clinical condition associated with some of the endocrine disorders. At St. Bartholomew's Hospital, under Professor Fraser, the medical unit has conducted a considerable amount of work of a biochemical nature. Drs. Linder and Carmichael have shown that the reduction of the chlorides in the cerebro-spinal fluid in cases of meningitis accompanies a corresponding decrease in the arterial blood serum and is not due to changes in the meningeal permeability. Professor Fraser, Dr. Linder, and Dr. Hilton have made observations on the circulation rate in man by a modification of the Fick principle. At Sheffield Professor Mellanby has continued his experiments to determine the chemical properties and the nature of the substance present in cereals which interferes with the calcification of bone. It has been shown that in this respect oatmeal is the worst and white flour the best of cereal products, and in the course of his work Professor Mellanby found that ergot had a decided antirachitic action, which is of interest in that as far back as 1889 Tanret first isolated ergosterol from ergot, and vitamin D must also have been obtained at the same time. At St. Andrews Dr. Rowand has made a further investigation into the occurrence of albuminuria in children, and he has also investigated the occurrence of respiratory catarrhs and the condition of the tonsils and adenoids in children of pre-school age. It is anticipated that these studies will eventually allow some valuable generalizations to be made.

CHILD LIFE.

Problems of the toxaemias of pregnancy have been investigated by Dr. O. L. V. de Wesselow at St. Thomas's Hospital. He has been occupied in a study of the blood volume and its relationship to the plasma protein content in the toxaemias of pregnancy in nephritis and hypertension. Work at Glasgow under the general direction of Professor L. Findlay on the metabolism of infants has been continued. Drs. Graham and Morris have been investigating the acid-base equilibrium with special reference to respiratory and gastro-intestinal disorders. Under Professor L. G. Parsons at Birmingham investigations into some aspects of the biochemistry of acute rheumatism have been continued, and, taken on the whole, the results indicate that the acid-base balance of the blood of rheumatic children is very little different from that of normal children. The work at this centre on coeliac disease has been continued, and the research has concerned itself chiefly with the source of the fat in the faeces. The evidence so far obtained points to the fat being unabsorbed food fat. At University College Dr. H. A. Harris has confirmed his views with regard to the role of vitamins in bone formation, and in Manchester Dr. A. A. Mumford has conducted an inquiry to determine whether, by the use of body measurements and physiological tests, any constant relation can be discovered between the varieties of physical build commonly found among adolescent schoolboys and the various physical activities and aptitudes which these boys display. Drs. Davies and Lightwood are investigating some of the factors concerned in the production of acute rheumatism in children under the age of 16, and Dr. Carey Coombs is supervising collective research on similar lines in Gloucestershire, Somerset, and Wiltshire.

HUMAN NUTRITION.

Under this heading last year some mention was made of an important investigation at St. Andrews. This involved inquiries into the dietaries of 159 households of all classes, carried out over a period of a week, and repeated for 35 households six months later. As St. Andrews is a non-industrial town this investigation has been supplemented by work at Cardiff, where the diet of some sixty households has been the object of study. Work on the importance of iodine in foodstuffs has been carried out at Aberdeen by Dr. A. B. Orr and Dr. I. Leitch. The report on this work has already been issued by the Council, and was noticed in these columns on February 16th (p. 307). With funds supplied by the Empire Marketing Board the Council has investigated the vitamin content of fruit, vegetables, and dairy products in relation to conditions of production, transport, and preservation. Dr. Zilva has been studying the mechanism of the inactivation of the active principle in lemon juice, and with Mr. Hoyle has undertaken an extensive inquiry into the antiscorbutic factor in apples grown in this country and stored for various periods under carefully controlled conditions at the Low Temperature Research Station, Cambridge. The behaviour of vitamins in butter and margarine kept in storage has also been studied.

(To be continued.)

TOXICITY TESTS FOR NEOSALVARSAN.

THE Medical Research Council has just issued a full report[1] of the inquiry conducted by Miss Florence M. Durham, Dr. J. H. Gaddum, and Mr. J. E. Marchal into toxicity tests for novarsenobenzene, concerning which Dr. H. H. Dale, F.R.S., gave a preliminary account to the international conference at Frankfort-on-Main in April, 1928. The attempt to achieve international uniformity in drugs of the salvarsan series brought to light a special set of problems. Unappreciated variations, or undetected accidents of manufacture, resulting sometimes in products unduly poisonous, have long called for the subjection of each batch of these drugs to a toxicity test. A number of arbitrary tests have been evolved, lacking, however, any common basis of comparison, and with no rational basis beyond that of vague practical experience. The means to a more reasonable conformity was found in the establishment of an internationally valid standard material for each important member of the series, samples with a higher toxicity being regarded as unfit for practical use. Following the acceptance of this standard the Medical Research Council's Department of Biological Standards undertook an experimental inquiry to ascertain what constitutes a suitable toxicity test, in the course of which the assumptions common to existing methods have been examined, and in many instances proved to be unsound. In particular, the inquiry has concerned itself with the influence of variability in the most uniform stock of experimental animals, and tables of probability have been drawn up which are applicable to the effects of different practical tests for the purpose in view.

General Purpose of the Test.

It has been suggested, on the hypothesis that toxicity and curative activity vary together, that as well as an upper limit of toxicity a lower limit is required below which it should not be allowed to fall. This hypothesis gets no support from the experience of these investigators, who assume that an independent test for therapeutic potency is applied, according to the recommendations of the International Conference on Biological Standards, which met at Geneva in September, 1925. This conference recommended that every batch of the remedies in question, before issue for use on human subjects, should be tested for therapeutic potency on mice or rats infected with a suitable strain of pathogenic trypanosomes, and that before being certified as fit for general issue it should have been used on a series of human patients under the supervision of a qualified expert. The conference at Frankfort further recommended, in emendation of the technique of the test proposed at Geneva, that samples of every batch should be tested for toxicity on at least ten mice or five rats, or on both, and only such preparations should be passed for issue whose toxicity under experimental conditions does not exceed the standard by more than 20 per cent.

Determination of the Characteristic Curve.

Though variations in sensitiveness to the same poisonous substances are known to occur even in a uniform stock of animals, the implications of this variability for the determination of a minimum lethal dose have not had the same general recognition. It is fortunate that the invariably lethal dose with most substances is many times as great as that which kills only an occasional animal. As a basis for practical measurement a dose must be chosen which kills a stated proportion of the animals treated, though the problem still remains of deciding what is to be regarded as a standard mortality. A lethal dose, as J. W. Trevan[2] suggests, can only be accurately stated as a proposition in probability. The larger the number of animals of a given stock which can be used in each investigation of a standard substance in a series of doses, the more closely will the experimental curve relating death rate to dosage approximate to the theoretical death-rate curve which can be given by an infinitely large number. When such a "characteristic toxicity curve" has been determined the death rate for any particular dose can be read off from it, and the probability that the actual death rate observed in a particular dose will differ from the theoretical death rate by not more than a specified amount can be stated numerically. Conversely, when an unknown quantity of poison has killed a certain proportion of experimental animals, the probability that the dose used differs by not more than a specified amount from the theoretical standard dose producing that death rate can also be estimated. With the data needed for the construction of a characteristic curve the investigators were able to decide on the dose and on the number of mice that had to be injected in order to obtain an accurate measure, within the defined limits, of the toxicity of the drug under examination. The ideal test would obviously be that which, on the one hand, allows every substance to pass if its real toxicity does not exceed that of the standard by more than the agreed proportion, and which, on the other hand, condemns every sample whose real toxicity exceeds the agreed limit. No practical test which passes every sample with a 20 per cent. excess will also inevitably reject every sample with a greater toxicity. It was found, however, that a test could be chosen which would pass a high proportion of drugs having a 20 per cent. excess and reject a high proportion of those in which the figure reached 30 per cent.

To eliminate any effects of variation in sensitiveness among different batches of mice injected on different days, and of variation in quality among the contents of different ampoules, the procedure was to take on one day a batch of mice and to inject an equal number with a range of doses made from one ampoule, and to repeat this until the required number for each dose had been injected. The dose for each mouse was calculated, in milligrams per gram, from its fasting weight, and the solution had a uniform strength of 2 per cent. All injections were made intravenously, and deaths occurring in the three following days were recorded. The first characteristic curve was obtained with mice taken at random, no attempt being made to choose mice of uniform stock or weight. The curve obtained could be regarded as giving only a general indication of the relation of doses to death rates. Further curves were made, using mice of approximately the same age, bred entirely from the laboratory's stock and selected so that their weights all fell within the limits of 18 to 20 grams. In view of the finding that, when the dose injected into each mouse was proportionate to its weight the mortality among small mice was lower than among large ones, a further experiment was undertaken, which established a relationship between dose and weight. Another fact observed was that the percentage mortality among female mice was invariably about 8 to 10 per cent. higher than among males. The investigators emphasize the fact that the curves they obtained relate only to mice of their own laboratory strain, and that each testing centre should therefore construct its own standard curve with mice resembling as much as possible those which would be used in routine tests.

Use of the Characteristic Curve.

The object of the test is not to determine toxicity, but simply whether or not the toxicity exceeds a certain maximum above the standard. The characteristic curve shows in what range the dose should be chosen, and by simple calculations from the available data it is possible to determine how many animals should be injected with that dose and what maximum should be fixed for the permissible death rate. The statistical department accordingly drew up a series of tables indicating, for different values of the probability that any one animal will die, the probabilities that in tests on five, ten, or fifteen animals the death rate will not exceed a specified figure. From the tables the investigators were able to obtain a figure showing the percentage frequency with which the standard itself would pass any test laid down in terms of dose, number injected, and maximum permissible mortality, and were thus able to deduce that any test showing a large percentage of failures of the standard would be unduly severe in its effect on good samples. A series of graphs was prepared, based on the characteristic curve, showing how often the standard preparation, injected in various doses, would be expected to pass a test on five, ten, or more mice. Toxicity is thus stated as "20 per cent. in excess" when the usual dose injected into a number of mice produces a mortality corresponding to that which a 20 per cent. larger dose of the standard would have produced; and the frequency with which a sample having that excess toxicity will pass can be found by taking the point on the appropriate curve which corresponds to a dose exceeding by the given percentage that actually injected.

Tests at Present in Use.

Tests requiring the use of mice are official only in Britain, Germany, and Japan, and the investigators proceeded to consider the validity of each of these tests separately, and of an alternative test prescribed in the American regulations for use when the mouse rather than the rat is chosen as a test animal. The British test, as applied to material having the standard toxicity, is satisfactory, the expectation of failure being only four in a thousand; but in relation to excess toxicity the test is not as discriminating as it should be. Of batches 10 per cent. more toxic, 20 fail out of 1,000, of batches 20 per cent. more toxic, 90 fail out of 1,000, and it is not until 90 per cent. excess is reached that rejection becomes practically certain. The German test, which involves the use of a large number of mice, is more discriminating than the British, and

[1] Reports on Biological Standards. II. Toxicity Tests for Novarsenobenzene (Neosalvarsan). Special Report Series, No. 128. 1929. H.M. Stationery Office. 9d. net.

[2] *Proceedings of the Royal Society B*, 1927, 101, 435.

batches of standard toxicity, and all but 1 per cent. of those having a 10 per cent. excess toxicity, passing the test; on the other hand, 38 out of every 100 batches with a 40 per cent. excess toxicity would still be able to pass. The Japanese test, when used with mice bred in the British laboratory, is unsatisfactory; 81 per cent. of batches with 50 per cent. excess toxicity pass the test, and it appears that a batch would have to be twice as toxic as the standard before its rejection became practically certain. The results of the American tests closely resemble those of the Japanese.

An Improved Test.

The investigators conclude that a more sharply discriminating test can be devised than any at present in use. Taking as their guide in the choice of a dose the fact that the greatest nicety is attained when the mortality rate rises rapidly with increase of dose, they find that, if 18- to 20-gram mice are used, an optimal dose is 7.6 milligrams per mouse. A 50 per cent. mortality produces the steepest curves in the above-mentioned graphs based on the characteristic curve, and thus gives the most discriminating tests. The final demand of their test is for a survival of at least 50 per cent. of thirty mice injected with 7.6 milligrams of the sample under examination. By conducting the tests in three stages, and eliminating from further tests those samples which are practically certain to fulfil the final demand and those which are certain of rejection, the number of samples requiring the full number of thirty mice is reduced to small proportions. All samples of toxicity up to the standard pass this test, and only 4 out of 1,000 fail when the toxicity is 10 per cent. above that of the standard. On the other hand, the test is unduly severe in that only 41 per cent. of material having a 20 per cent. excess of toxicity can be expected to pass it. The stringency, however, can easily be modified without sacrifice of precision by raising or lowering the standard dose and keeping the mortality constant.

Need for a Standard.

The investigators conclude by stressing the need for a uniform and practically stable standard. Comparative biological testing of any substance is possible only when a standard can be prepared and stored in such stable form that samples can be trusted to retain their value for a reasonable time after distribution. In relation to novarsenobenzene, they are convinced that such stability may be ensured with a selected and tested batch, desiccated with great care and thereafter kept at low temperature, and they suggest that the adoption of the precautions recommended by the international conference at Frankfort will soon render available a stable central standard.

Ireland.

The Four Provinces Club.

THE Four Provinces of Ireland Club held its annual banquet and ball at the Hotel Cecil, London, on March 18th, with the president, Mr. J. B. Melville, K.C., in the chair. Among the very large and distinguished gathering of Irishmen and Irishwomen and their guests were a considerable number of members of the medical profession. The chairman and others at the high table were played into the hall by Shaun O'Neill's Irish Pipers; grace was said by the Right Rev. Dr. Amigo, Bishop of Southwark; and during dinner Irish airs were played by the string band of H.M. Irish Guards. After the King's health had been honoured, the toast of "Ireland" was proposed in eloquent and sympathetic terms by Mr. Justice McCardie. The first reply was by Mr. O. Grattan Esmonde, a member of the Dail, who brought a message of congratulation from President Cosgrave; and the second (a model of its kind) by Sir William Wheeler, who reminded his English and Scottish friends that in Ireland there was a close alliance between Literature, Medicine, the Church, and the Law, all of which callings had leading representatives among them that night. If he were asked by a great insurance corporation to report on the health of Ireland, Sir William Wheeler said he would reply that she was a first-class life, and might reasonably be accepted at a reduced premium, but if asked how that health could be maintained, or even improved, he would advise against too rich a diet of undiluted Irish politics. In the twentieth century the social, scientific, and economic interests of all countries were so interlocked that an unrestricted policy of detachment from a neighbour might lead in the case of any nation to a heart-breaking process of decay. Science and letters knew no nationality and no distinction of race or of speech, but they did recognize that their contributions should be dedicated to the service of mankind, and should be worthy of the country from which they sprang. The Four Provinces of Ireland could hold up their heads in this respect. In surgery there was Berkeley Moynihan, whose forefathers came from Munster; and Hugh Rigby, born in Dublin, who had been chosen to operate on the King. Sir William Wheeler also recalled the name of Alfred Keogh, hailing from Connaught, who, as Director-General of Medical Services at the War Office during the war, was the master mind which coped with casualties amounting to almost three million on the Western Front alone. He mentioned, further, a devoted scientist screened from the public gaze, Professor John Joly of Trinity College, Dublin, who had been the force behind the discovery of how to collect radium emanations in such an economical way that they could be used in the treatment of cancer among the poor in every land. Thus science and literature and their allies ranked co-operation high above checkmate, and joined in brotherhood in the service of mankind. The concluding toast of the evening was that of "The Guests," proposed in the warmest manner by the Chairman, and responded to by Lord Justice Russell, Mr. R. D. Blumenfeld, and Mrs. C. J. Mathew, L.C.C. A small reproduction from the beautifully illuminated menu card appears on this page.

FOUR PROVINCES OF IRELAND CLUB.

County Medical Officers of Health in the Irish Free State.

Considerable progress in the appointment of county medical officers of health has been made under the Local Government Act, 1925. In co. Cork a chief medical officer of health has been appointed, with three assistants to carry on the general functions of medical officers of health under his supervision; a chief public health nurse, with six whole-time assistants, has been obtained for school inspection and tuberculosis work. In Kildare and Offaly county medical officers of health have been installed to deal with school inspection, tuberculosis, and other public health work. In counties Louth and Cork the county medical officers of health, in addition to their other duties, are pushing forward with a scheme for the eradication of diphtheria by immunization. Carlow and Westmeath have recently appointed county medical officers of health, and the question is under consideration in at least half a dozen other counties. As regards the four county boroughs, school medical services have made considerable progress in Dublin and Cork, and schemes are now being inaugurated in Limerick and Waterford. Since the appointment of county medical officers of health the notification of infectious diseases and other public health records has greatly improved. In the development of these schemes the Department of Local Government and Public Health has received considerable help from the Rockefeller Foundation.

Tuberculosis in Meath.

At a recent meeting of the Meath Board of Health a letter was received from the Department of Local Government and Public Health pointing out that immediate steps should be taken to bring into operation a suitable scheme for the treatment of tuberculosis in the county, and suggesting that the arrangements should be co-ordinated with other county health services under a county medical officer of health. Dr. Sterling Berry, medical inspector of local government and public health, who attended from the Department of Local Government, said that in 1927 the number of deaths from pulmonary tuberculosis in Meath was sixty-six, and from other forms of tuberculosis twenty-five. If they had a tuberculosis medical officer in the county no doubt a number of these cases would be discovered in the earlier stages of the disease, which was especially necessary in pulmonary tuberculosis, if they wanted to save life. In other forms of tuberculosis—surgical—even if the patient did not die as a result of the disease, he was generally crippled for life and likely to become a charge on the rates. Dr. Berry said he had been looking into some figures in connection with co. Meath, and, considering the nature of the county, some of these figures had startled him. In Meath in 1927 the figure for childbirth deaths was 3.27; in 1924, 3.27; in 1925, 5.95; while in 1926 there were fifty deaths from congenital debility and premature births in this county. In his own district, which embraced some of the poor western districts and which were not in the same category as Meath, the figures were nothing like that. The county medical officer of health would be responsible for maternity and child welfare, and for the inspection of school children. It was a statutory obligation on the county councils to have an inspector of midwives, and this duty would be undertaken by the county medical officer of health. Considering the figures he had given it was quite evident that this officer would be a great advantage in Meath. He could be chief tuberculosis medical officer and medical inspector of school children. Fifty per cent. of the salary as such was repaid by the Government, and when the officer found a child requiring dental treatment or treatment for adenoids half the cost was met, even though the children were treated in their own hospital. So far as the county medical officer of health was concerned, all the Board of Health could do was to send a recommendation to the county council, which had the responsibility of paying. But the Board of Health, as the health authority for the county, could tell the county council that they considered it was time to move in that direction. The medical inspection of school children, Dr. Berry added, was a splendid thing; they were examined by an expert, the disease was detected in the pre-tuberculous stage, and was then arrested. The section gave the Minister full power to ask the Appointments Commissioners to recommend a person in case the county council did not do so. If the county council appointed the man themselves at a salary of, perhaps £800 a year, that might be allocated on the basis of £450 as tuberculosis medical officer of health, and the remainder as school medical officer and inspector of midwives, say £500 or £600, for half-recoupment. The travelling expenses would be dealt with similarly. There was no recoupment in respect of the county medical officer of health.

General Nursing Council (Irish Free State).

At the first meeting of the newly constituted General Nursing Council Sir Edward Coey Bigger and Miss O'Flynn were unanimously elected chairman and vice-chairman respectively. It was reported to the council that the total number of nurses registered in the Irish Free State was 4,881. This number includes 3,869 general, medical, and surgical nurses, 3 male nurses, 901 mental nurses, 44 sick children's nurses, and 64 fever nurses. At the last examination held by the council in Dublin, Cork, and Waterford there were 219 candidates, 21 of whom failed. The council passed a resolution calling on the Minister for Local Government and Public Health to take such action as may be necessary to ensure the appointment to permanent posts in mental hospitals throughout the Free State of only those mental nurses who are fully trained and registered. From their number the council appointed rules, registration, finance, uniform, and badge committees. The penal cases will be considered by all the members of the council. Dr. Kelly, Dr. Leeper, and Dr. O'C. Donelan were appointed to act as an advisory committee to the council in matters connected with mental nursing.

England and Wales.

The Burrow Hill Sanatorium Colony, Surrey.

It is proposed to reopen next month the Burrow Hill Sanatorium Colony at Frimley, in connexion with a new scheme—namely, the treatment and training of tuberculous youths between the ages of 14 and 19. This colony, which is administered by the National Association for the Prevention of Tuberculosis, was originally started for tuberculous ex-service men, and now that the need for it in this respect has been met, a new field of utility is being opened up with the active co-operation of the Ministry of Health. The scheme has been approved by an order of the charity commissioners, provided that preference is given to the dependants of ex-service men. The institution will contain eighty beds, sixty of which are to be available for arrested cases of tuberculosis, while the remainder—in a specially designed block—will accommodate patients in the earlier stages of the disease. While primarily intended for youths suffering from pulmonary tuberculosis, in whom permanent arrest of the disease is ultimately likely to be secured, and who need technical education with a view to being enabled to support themselves economically, cases of glandular tuberculosis without sinuses, or of tuberculous disease of the bones and joints, will also be eligible for admission provided that active orthopaedic treatment is no longer required. Since technical education forms an essential part of the regime, only those who are physically and temperamentally suitable for it can be dealt with. This education will comprise gardening and clerical work; the course in gardening has been prescribed by the Surrey Agricultural Department, and the clerical work will be under the supervision of the Surrey Education Committee. It is hoped that the subsequent placing of the youths in employment will be effected by care committees or other organizations responsible for this kind of work; in some cases promises of employment may be obtained in advance, when efforts will be made to arrange the training of the individual so as to fit him for the particular post. The duration of residence contemplated is one year, or longer, and the inclusive cost of maintenance will be 50s. a week. Facilities will soon be available, therefore, for local authorities in England and Wales who are concerned with the long-period treatment and technical education of tuberculous youths. The Minister of Health has issued to county and county borough councils and tuberculosis joint committees a circular (969) notifying them of the establishment of this institution, and advising them to make use of it. Emphasis is laid on the importance of selecting patients who will be able to remain for as long as may be required; and the hope is expressed that the tuberculosis care committee, or other suitable organization, will charge itself with the task of finding suitable employment for patients on discharge.

Central Midwives Board.

The Central Midwives Board for England and Wales met on March 7th, when Dr. West presided. A letter was read from the acting registrar of the Nurses' Registration Board, New South Wales, asking the Board's views on a proposal to extend the period of training from twelve months to two years for pupil midwives who were not general trained nurses. It was agreed to reply that the period of midwifery training in England has only recently been increased, and that sufficient time had not yet elapsed to enable the Board to express an opinion as to the advisability of extending the period still further. With reference to a letter from the Cheshire county council—which considers the forms for keeping ante-natal

notes, as prepared by the Board, too complicated, and asking approval of one, a specimen of which was forwarded—it was decided to reply that the Board was proposing to consider, in due course, and in the light of experience, a revision of the form of keeping ante-natal notes, but that the existing form was intended for well-trained midwives, and that midwives not sufficiently well trained should be instructed in the method of using the form. Midwives who needed instruction should be advised to take their patients to an ante-natal clinic, and, if this was impracticable, arrangements should be made for a medical examination. The Board did not see its way to approve the form submitted as a substitute for the official one. A letter from the medical officer of health for the county of Southampton was considered. It was stated that a midwife had summoned a doctor for a patient suffering from "severe frontal headache" on the seventh day of the puerperium. The doctor had paid more than one visit and the medical officer of health inquired (1) whether the condition, as described by the midwife, constituted an emergency as contemplated by the rules, and (2) whether the committee would be justified in informing the doctor that, while his account would be paid on this occasion, in the event of his being sent for by a midwife in similar circumstances in future, payment could only be made for the first visit, the ground for such decision being that the condition as described was not a complication of pregnancy. The medical officer of health also suggested that Rule E 21 limited the operation of Rule E 20 to cases which were direct complications of pregnancy and confinement, and asked for the Board's opinion on the point. It was resolved to reply that, inasmuch as the Board had always held that Rule E 20 applied to *all* cases of illness or abnormality occurring during pregnancy, labour, or lying-in, without being restricted in any way by Rule E 21, the Board was of the opinion that the condition referred to in the letter was an emergency within the meaning of Section 14 of the Midwives Act, 1918. The question of payment of fees to doctors under Section 14 of the Midwives Act, 1918, was one for the Minister of Health and not for the Board to decide. Dr. Fairbairn and Dr. Lyster reported on their inspection of the new maternity hospital in Wolverhampton, and on the question of midwifery training there. It was decided that the recommendations of the report should be communicated to the hospital, and that the observations of the hospital authorities thereon should be invited.

Conference on High-grade Milk Production.

A conference is to be held at Reading on April 16th and 17th, under the auspices of the Certified and Grade A (Tuberculin Tested) Milk Producers' Association, for the discussion of matters of mutual interest to those concerned in the production of the highest grades of milk. The chairman of the conference on the first day will be Sir George Newman, Chief Medical Officer of the Ministry of Health, and on the second day Professor Frederick Hobday, principal of the Royal Veterinary College, London. The mornings are to be devoted to papers and discussions, and the afternoons to visits to producers' farms and the premises of distributors in the district, as well as to the University farm and the National Institute for Research in Dairying. The subjects for discussion include the progress of the movement for graded milk in England and Wales, Scotland, and Northern Ireland, the production of tuberculin-tested milk in Holland, the use of milking machines, the variation in the fat content of milk, and the relative values of milk raw and heated. Among the readers of papers are Professor Stenhouse Williams, Dr. R. M. F. Picken, medical officer of health, Cardiff, and Major G. W. Dunkin, of the National Institute for Medical Research, who is to speak on the tuberculin test. The authorities of Reading University are actively co-operating by allowing the conference to be held at the University, and by placing hostel accommodation at the disposal of the visitors. The honorary secretary of the convening association is Lieut.-Colonel C. Maddock, M.D., D.P.H. (Foxglade House, Shinfield, Reading), to whom any communications should be made.

District Nursing in London.

Steady extension of the work of the Central Council for District Nursing in London is a prominent feature of the report of the council for 1928. Notable improvements have been effected in South London, and better nursing arrangements are being made in the new London County Council estate within the Hendon Urban District. A new association has been started in Middlesex for Sunbury, Upper Halliford, and Charlton, in affiliation with the Queen's Institute; this association will be conducted on a provident basis, the payment of 2d. a week being asked. The appeal fund was closed in October, 1928, the amount received being £1,700. About half this sum was distributed last July in order to maintain the amount of awards to associations at the level of recent years; the remainder has been placed on deposit. An appeal for help to King Edward's Hospital Fund was unsuccessful. The total awards made to district nursing associations in 1928 amounted to £4,443, including the sum received from the appeal fund. In addition to the £3,000 entrusted to the council by the trustees of the London Parochial Charities, £400 was also given by these trustees for the administrative work of the council, and £100 was granted for bursaries. Contributions were also received from the Worshipful Companies of Drapers, Cloth Workers, and Skinners, the Society of Apothecaries, and the Peabody and Guinness trustees. A sum of £533 was paid through the council by the Ministry of Health in respect of midwifery and maternity nursing undertaken by certain associations. The British Medical Association is represented on the central council by Mr. Comyns Berkeley, Dr. William Paterson, and Mr. H. M. Stratford.

Arrangements for Dealing with Venereal Disease in London.

The proposed arrangements for the diagnosis and treatment of venereal disease in London for 1929–30 were placed before the London County Council on March 12th. Seventeen general and six special hospitals now undertake in-patient or out-patient and other work under the scheme, and all-day clinics have been provided at St. Thomas's, Guy's, the Royal Free, and St. Paul's Hospitals. An all-day clinic at the London Hospital is expected to be available at an early date, and another at the West London Hospital is in course of construction. Six hostels are also included in the scheme. The county of London, for the purposes of these arrangements, is joined by certain neighbouring authorities—namely, the councils of the counties of Buckingham, Essex, Hertford, Kent, Middlesex, and Surrey, and the county boroughs of Croydon, East Ham, and West Ham. During 1928 the number of new cases which came forward was 25,996, of which, however, 9,595 were found to be not venereal. The number of venereal cases (16,401) shows a decline on preceding years: the average for the years 1924–27 was 18,077. Of the new cases in 1928, those of syphilis numbered 5,270, of gonorrhœa 10,896, and of soft chancre 235. It is pointed out that these figures are not the full measure of the extent to which venereal disease came under treatment in London, as a not inconsiderable number of cases received treatment by general medical practitioners. The number of bacteriological specimens examined at the hospitals at the request of, and free of cost to, practitioners in all areas was 29,406, and 459 practitioners are on the approved list for the free supply of salvarsan or its substitutes. The total expenditure estimated for 1929–30 is £103,760, of which 83 per cent. represents London's proportion, and 17 per cent. that of the participating authorities; three-fourths of the expenditure is recoverable by Government grant.

Royal Bath Hospital, Harrogate.

Presiding at the one hundred and third annual meeting of the Royal Bath Hospital and Rawson Convalescent Home, Harrogate, Viscount Lascelles commented on the need for spending more money on research with a view to preventing rheumatic complaints. The annual report of the committee of management showed that the progress of the institution had been steady and satisfactory. The most urgent needs were the provision of an

electric lift and of a suitable theatre for minor operations of an orthopaedic nature so as to deal more efficiently with serious cases than was at present possible. Special donations were invited for these urgently needed extensions, which were only being delayed for lack of money. Other requirements were an *x*-ray plant and facilities for occupational therapy. The treasurer reported that the hospital balance sheet showed a profit on the year's working of about £500, and the Home a profit of £117. The laboratory account revealed a substantial deficit, and the treasurer emphasized the importance of obtaining an endowment of between £8,000 and £10,000 to provide the necessary income in this respect.

Correspondence.

A COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

SIR,—Dr. Herbert Spencer's letter (March 16th, p. 523) has appeared at a critical moment in the history of a great endeavour to establish a British College of Obstetricians and Gynaecologists—at the very moment, in fact, when we are presenting our case, and the objectors theirs, to the judgement of the Board of Trade, at which an inquiry is to be held on Friday, March 22nd, the day on which this issue of the *British Medical Journal* will be published.

I am sure Dr. Spencer's intention is not to put a spoke in our wheel, but merely to represent the other side of the case, which, in various forms, has been laid before us during our deliberations extending over a period of four years, and which has been rejected by us as being apprehensive rather than apprehending.

It is clear, I think, that Dr. Spencer is as anxious as the rest of us are about the present unsatisfactory position of obstetrics and gynaecology—a science limited no longer (in the language of the Chinese) to the "regions below the belt," but embracing many aspects of medicine and surgery, to both of which, indeed, it has itself largely contributed. Nevertheless, physicians and surgeons in the past (there are many enlightened exceptions to-day) have treated gynaecology and obstetrics rather disdainfully as an offshoot, and not as a partner of equal rank.

Our art, which is as old as theirs, and which has also attained to the position of a high biological science, has become differentiated, and cannot any longer be absorbed or suppressed in the progress of evolution: it has its own individuality and ideals, which must find expression at the hands of its own exponents. But while Dr. Spencer seeks to find alternatives to the formation of a new college, and suggests that the various objects we have in view fall within the province of the Obstetrical Section of the Royal Society of Medicine, the medical press, and the Royal Colleges of London, the fact remains that in a period of very many years these alternatives have not materialized. Dr. Spencer evidently has missed what seems to be the reason—namely, unified and concerted effort is necessary to obtain great results. All the bodies mentioned have undoubtedly rendered great service to one cause or another, but none of them has lifted, or, I suggest, has seriously tried to lift, obstetrics and gynaecology from the rut along which it would have travelled indefinitely if it had not been idealized and raised to its present position—academic and practical—by ardent votaries.

At present there are many gynaecological and obstetrical societies scattered throughout Great Britain which are doing work no less valuable than that of the Section devoted to this subject at the Royal Society of Medicine; there are, moreover, colleges elsewhere as important in the eyes of their disciples as are the London colleges in the opinion of those of us who have the honour of belonging to them. The time has now come when the various scattered groups of obstetricians and gynaecologists, while remaining attached and loyal to their own colleges and societies, should bind themselves together in one corporate body to advance their specialty. That, then, is the real issue. Are we to be content with playing for our counties only, or may we not aspire to constitute from our county membership an M.C.C. to represent not only London, but the whole country?

This is not the place, nor is the present the proper time, to go into the arguments and details which will be carefully considered in a few days' time; but I wish, in closing, to make clear the fact that, if we succeed in our application, we shall all fully realize that there are before us long years of spade-work and probation, during which we shall try not only to justify our existence, but also by discipline, hard work, and vision to create a great tradition, and to acquire a home, a library, and that financial status the value of which Dr. Spencer by no means overestimates.—I am, etc.,

W. BLAIR BELL,
Chairman of the Council of Signatories of the proposed College of Obstetricians and Gynaecologists.

Liverpool, March 16th.

P.S.—I regret that time and distance have not allowed me to consult any of my fellow signatories, or to obtain their valuable co-operation in drafting this letter, but I have endeavoured briefly to express in a general way views which, I believe, we hold in common.—W. B. B.

COLLES'S FRACTURE.

SIR,—The discussion in your pages on Colles's fracture grows more complicated each week, as each contributor puts forward a new suggestion, whilst the general principle essential to success in the treatment of any fracture is being overshadowed. Every writer agrees that perfect anatomical reduction is essential, but not one has mentioned the only possible way in which this can be ensured. It matters not what manœuvre is practised—whether the ulna is pushed backwards or the radius forwards—whether one uses one's hands or a wedge—whether one prefers gas or ether—provided that the success of the manœuvre is proved by the immediate post-reduction *x*-ray examination through the splints.

Whether Mr. Bankart agrees or not as to the possibility of reduction by Sir Robert Jones's method under gas anaesthesia, the fact remains that at the Liverpool Royal Infirmary over 400 cases a year are being successfully treated by this method by house-surgeons and house-physicians. But it must be emphasized that the house-surgeon's treatment is controlled, and that every case without exception is returned for a second *x*-ray examination, and inspected the following morning at the daily fracture clinic by the orthopaedic surgeon. If the position is not absolutely perfect the fracture is again manipulated and *x*-rayed as frequently as may be necessary to secure anatomical perfection. Not until then is the patient transferred to the weekly clinic.

In this way the house-surgeon gains as much experience as he wishes, and yet treatment is so controlled that our follow-up clinics show that in 80 per cent. of our cases it is difficult or impossible after twelve months to distinguish the fractured from the normal wrist. These results are secured by the routine described by Sir Robert Jones, except that I always teach house-surgeons to use the manipulative manœuvre in its two component parts, the backward displacement and tilt being corrected by one movement, and the outward displacement by a second. Unless these are practised individually and separately there is a tendency to leave the outward displacement slightly under-corrected, so producing a bad cosmetic result owing to radial deviation of the hand, and a bad functional result owing to arthritis of the lower radio-ulnar joint. A pad over the back of the distal fragment and one over the front of the proximal fragment, with two gutter splints of aluminium, the posterior extending to the knuckles and the anterior falling short of the thenar eminence, provide an entirely adequate, simple, and comfortable method of immobilization.

But individuality is the keynote of surgery, and such details are of no significance as compared with the three essential principles: (*a*) anatomical reduction proved by *x*-ray examination; (*b*) immobilization for a month; (*c*) full finger movement from the first day.—I am, etc.,

R. WATSON JONES.

Liverpool, March 17th.

SIR,—The discussion on Colles's fracture at present taking place in the *Journal* must be of extreme interest to the profession. Anything that can help in overcoming or lessening the disability must be welcome to both the doctor and patient. This is my reason for adding to the discussion a simple line of treatment I have adopted to all fractures for some time past—namely, three-quarter to an hour's massage (by a masseuse) immediately before any attempt is made to reduce the fracture. It is very striking how easily a Colles's fracture can be disimpacted and completely reduced without causing pain to the patient. —I am, etc.,

Bath, March 12th. JOHN S. LEVIS.

ENLARGEMENT OF THE PROSTATE.

SIR,—The valuable discussion which has taken place in your columns recently has had its scope widened by the interesting letter from Mr. Andrew Fullerton (March 2nd, p. 417). I wish to support wholeheartedly this writer's statement regarding the use of an indwelling catheter. The two-stage prostatectomy has been unknown in my practice for several years. I could instance case after case similar to those cited by Mr. Fullerton and bearing out his claims, where men suffering from chronic urinary retention, *and showing dry, furred tongues and parchment-like complexions*, together with a high blood urea and all the other evidences of chronic uraemia, have recovered their health within a week or ten days sufficiently to undergo a successful prostatectomy. *It is a constantly recurring experience to* have patients admitted with a blood urea of 80 to 100 mg., and to watch this figure fall within a week or so to the neighbourhood of 40 mg., with a corresponding improvement in the patient's appearance and in his *sensation of* well-being, this resulting solely from the employment of an indwelling catheter. It should be observed, however, that the catheter must remain in the bladder. *Similar results* cannot be obtained by passing the instrument two or three times daily, as is done by some surgeons. *During this* period the bladder is irrigated twice or thrice each day, and *on each occasion two ounces of mercurochrome are clamped* in the viscus for a quarter of an hour and then released. Though some sepsis may occur in spite of these precautions, I maintain that it is materially less than that caused by a preliminary suprapubic drainage, and that those who fancy they can reduce cystitis prior to prostatectomy by that preliminary operation deceive themselves.

The simplicity of the procedure, the avoidance of a duplicate operation, and the incomparable blessings of a clean field for the main operation are notable assets. Moreover, the mortality during this drainage period is very small and compares very favourably with a definite death rate which I know to occur in the practice of those who do the double operation.

The employment of a finger in the rectum should be abandoned. It is unnecessary, and it is dirty. Even if two gloves are worn, as recommended, and the upper one is changed, the sleeve is nevertheless soiled. Nor is it desirable to remove the glove from the enucleating hand. The prostatic adenoma in the vast majority of instances forms an incomplete collar encircling the urethra in its posterior four-fifths. If the enucleating finger is gently passed into the prostatic urethra it will easily detect the anterior limit of this collar (anterior end of lateral lobe). The force required to commence enucleation at this point is so slight that the gloved finger can *accomplish it without tearing the* glove. This is not the region described by Freyer, nor, indeed, by many subsequent writers, but it nevertheless gives the quickest and easiest access, and merits the attention of any who have not yet tried it. *Some of them will not then* find it necessary to devise excuses for the use of the naked hand.

I agree with Mr. Fullerton that Sir Henry Thompson's dictum that enlargement of the prostate does not occur before the age of 50 requires revision. I have myself operated upon three cases below that age, and know of at least two others operated upon by other surgeons. Moreover, the number of men who present themselves suffering from the results of prostatic hypertrophy within a year or so of reaching the half-century has recently impressed me considerably, symptoms having occurred in not a few prior to reaching that milestone.—I am, etc.,

Manchester, March 12th. JAMES B. MACALPINE.

CYCLICAL VOMITING.

SIR,—In the report of the discussion upon the chronic dyspepsias of childhood at the Medical Society in your issue of March 16th (p. 502) Dr. Reginald Miller is *reported* as quoting a statement of mine to the effect that 30 per cent. of hospital children suffer from cyclical vomiting. There is even a footnote giving a reference to page 185 of your issue of February 2nd, which might lead the reader to suppose that Dr. Miller had found such a statement in some writing of mine.

I do not know the frequency of cyclical vomiting and have never made any attempt to state it. I certainly see numerous cases at the hospital, but then a good many are sent to me specially because my friends know I am interested in this particular disorder. Even so, the total is nothing like 30 per cent. of all the cases I see.—I am, etc.,

London, W.1, March 18th. H. CHARLES CAMERON.

LOCAL ANAESTHESIA IN OPERATIONS FOR HAEMORRHOIDS.

SIR,—*Dr. T. H. T. Barber's paper in your issue of* March 2nd (p. 397) and the subsequent papers by Sir William Wheeler and Mr. W. B. Gabriel should help to popularize a now well-established method of producing anaesthesia for operations upon the rectum and anus. I would like to sound a note of warning in case the incautious use of this method by those who are not well accustomed to local anaesthesia should result in accidents and tend to discredit local anaesthesia in these cases.

Both novocain and adrenaline are very safe drugs unless they are inadvertently injected into a vein; if this should happen even very small doses will cause most dangerous symptoms. The anal region is particularly rich in large veins, and it is most important that care should be used to avoid injecting the solution directly into the venous plexuses. My own practice in using local anaesthesia in operations for piles or fissure is to inject a 1 per cent. solution of novocain under the skin round the anus, starting at the posterior commissure and working forward on both sides till the whole anal cutaneous margin is anaesthetized, and then to pass the needle into the external sphincter guided by a finger in the rectum. The sphincter is very easily anaesthetized in this way and will quickly relax. A further injection into each ischio-rectal fossa will ensure complete anaesthesia of the whole region and allow of the rectum being properly washed out and sterilized, without which no operation upon the rectum is justified.

Personally I prefer not to use adrenaline at all, as I consider that it is more dangerous than novocain should it accidentally get into a vein, and quite excellent anaesthesia can be obtained without using it. I am sure that many accidents attributed to cocaine and novocain have in reality been due to the adrenaline added to them.—I am, etc.,

London, W.2, March 15th. J. P. LOCKHART-MUMMERY.

SIR,—In reply to Sir William Wheeler's letter, on March 9th, regarding my article, which was published on March 2nd (p. 397), I am very gratified to note that he fully supports my thesis by his own valued experience, and that he agrees with my own findings as to the superiority and advantages of local anaesthesia *versus* a general one for these operations. I also observe that he gets equally good results by the use of a simpler method of injections, but that he does not approve any stretching of the external sphincter, and attributes some of the after-pains to this practice.

I quite agree that, for purely operative measures, the complete relaxation obtained at the time of the operation

by the injections is all that is required, but I think that physiological rest for the parts for some days is necessary, and can best be obtained by induced temporary paralysis or abolition of tonicity by stretching the sphincter ani. For the cure of simple non-complicated fissures this may be all that is required. Frequently I have performed a dilatation operation at a nursing home in the morning, the patient returning to his own home the same evening without complaining of pain, and, when necessary, taking up his occupation on the following day. From these experiences I personally do not find that dilating the sphincter materially increases after-pains. With careful dilatation retention of urine should not occur.

Cutting, or the removal of any skin, is, I think, the chief cause of after-pains, and, in complete accordance with Sir William, I believe that no skin should be removed, that no raw surface or edge should be left unsutured, and that careful suture tends not only to lessen after-pain, but prevents spasm, post-operative haemorrhage, and infection.

Butler, in his *Textbook on Materia Medica, Therapeutics, and Pharmacology* (p. 392), says: "Antipyrine . . . analgesic and local anaesthetic. As an analgesic it probably ranks next to opium. The anaesthesia produced by antipyrine lasts for several hours or even days." Perhaps my employment of antipyrine—in vaseline—freely in all cases of simple dilatation, or after any kind of operation on the anus or rectum, may in a great measure be responsible for the minimum of after-pains noticed in all these cases.

Mr. W. B. Gabriel (March 9th, p. 474) draws attention to a very important point—namely, that no perianal swelling or oedema is seen after local anaesthesia (as contrasted with general narcosis), because there is never any vomiting. These complications may be the source of considerable pain or discomfort, lasting for several days after the operation. Following operations under local anaesthesia (the method of performing them is a secondary consideration, the most efficacious and simplest being, doubtless, the best) patients, on returning to bed, feel quite able to have something to eat or drink, and often enjoy a smoke; they are quite comfortable for from five to *seven hours after the operation, when pain may occur*, and last for several hours, though it never becomes intolerable. I suggest that this method, as endorsed by Sir William Wheeler and by Mr. Gabriel, is in all respects superior to any general or spinal anaesthesia.

Further, I think, that for the relief of post-operative pain, the systematic use of antipyrine should be given a fair trial; incorporated in vaseline it may be used immediately after the operation and for all subsequent dressings. It can be associated with any antiseptics that are not chemical incompatibles.—I am, etc.,

T. HENRY TREVES BARBER, M.D., B.Sc.

London, S.W.7, March 12th.

SIR,—I would like to endorse the opinions expressed by Dr. Barber (March 2nd, p. 397) on the advantages of local anaesthesia for the operative treatment of haemorrhoids and their complications. I have used local anaesthesia extensively for the past twelve years, especially for the ligature of haemorrhoids too fibrosed for effective treatment by sclerosing injections (the treatment of choice for simple or uncomplicated piles), and consider that it makes a combination of ligature and injection the ideal treatment when simple and complicated piles coexist. "Simple" haemorrhoids contain only varicose veins whose walls are not markedly fibrosed (*about 50 per cent. of all pile cases*), and "complicated" haemorrhoids may contain thick-walled veins, arteries, dense fibrous tissue, and another lesion—for example, fissure may coexist. A recent case will serve as illustration.

A male patient, aged 31, gave a history of prolapsed bleeding haemorrhoids of several years' duration. He had had to give up riding and sport. Examination showed five haemorrhoids, two small ones, three very large and fibrosed, two of the latter being intero-external. I injected the two small ones and removed the three larger by ligature under local anaesthesia. The patient had no pain or discomfort during the operation, and very little afterwards; he even refused a sedative that night, and was up on the second day, gentle exercise being allowed until healing was complete. Both the patient and his doctor have since warmly expressed their satisfaction at the result.

In sparing as much of the rectal mucous membrane as possible (by injection) and employing local anaesthesia for ligature, post-operative complications, such as stricture of the rectum, retention of urine, pain, and the period of lying up, are reduced to a minimum.

The anaesthetizing solutions I have chiefly used are: 1 per cent. quinine and urea hydrochloride, and a novocain solution somewhat similar to Dr. Barber's; each gives excellent results. Their advantages are that they are practically non-toxic and can thus be used in large dosage, they have a prolonged anaesthetic effect, and are haemostatic.

The technique I employ is simple and effective. It consists of deep infiltration to anaesthetize the sphincter and the tissues underlying the haemorrhoids. This is effected by means of four or five injections equi-spaced around the anus as follows. A 5 c.cm. syringe with a very fine needle 2 inches long is used. The skin at the point of injection is anaesthetized by injecting a few drops subcutaneously, and, by pushing the needle along under the skin, the points for further deep injections are anaesthetized so that only the initial needle-prick is felt. At a point on the skin half an inch from the anal opening, the needle is inserted downwards and slightly inwards through the sphincter to a depth of 1½ in., care being taken not to penetrate the bowel wall and inject anaesthetic into the rectum. A gloved finger in the bowel should obviate this by guiding the needle to its destination. Having reached the tissues underlying the haemorrhoid the solution is injected slowly drop by drop as the needle is gradually withdrawn. After three to five minutes anaesthesia will be complete. I have never found it necessary to apply the solution to the surface of the haemorrhoid nor to inject the anaesthetic into the body of the pile. Quinine and urea, whilst excellent for deep infiltration, should not be employed to anaesthetize the skin, as it causes thickening and induration of the cut edge. About 2 c.cm. of these solutions is necessary for each injection, but experience alone will teach the correct amount, which varies for different patients. Hirschmann has advocated local anaesthesia, both in writings and at British Medical Association and other medical meetings in this country, for over twenty years.

In my view Mitchell's operation should be abandoned in favour of the simple "ligature" advocated by proctologists in this country, which entails only a single cut with the scissors. Ano-rectal operations involving suture, of which Mitchell's is an example, *should rarely be practised*, as free drainage is essential in this region if sepsis is to be avoided. Stretching of the sphincter ani is seldom necessary; it frequently causes much pain, bruising, and damage to the sphincter with varying degrees of loss of control. Insertion of large rubber tubing after operation is unnecessary, and is a common cause of severe pain. Many times as a house-surgeon I answered the agonized appeal of some poor patient to take the tube out, and the relief from pain was always immediate. Haemorrhage after a skilfully performed ligature operation is uncommon.

The combined ligature and injection method causes the least pain, fewest complications, and shortest lying-up period. It is suitable for every type of case except where large sloughing haemorrhoids exist. Local anaesthesia is contraindicated in the latter condition.—I am, etc.,

P. KENNEDY MURPHY, M.D.

London, W.C.1, March 7th.

A NEW METHOD OF APPROACH IN GASTRIC SURGERY.

SIR,—In reply to the letter of Dr. *Roberts in your* issue of March 9th (p. 474), I may say that the object of the experiment was to determine the effect of a single massive dose delivered directly to the growth. *The purpose* of my article was to state the effect observed and the result obtained.

I regret I did not enclose the technical details of the radiation. These I have now obtained from Dr. Cooper, and they are as follows:

Secondary current 3 ma.; secondary voltage 190 kv.; filter 0.5 mm. Cu+0.3 mm. Al; focus-skin distance 23 cm.; exposure 40 minutes. Dose 1.5 E.S.D.

—I am, etc.,

DIGBY CHAMBERLAIN, CH.M., F.R.C.S.

Leeds, March 12th.

"EXANTHEMATIDES."

SIR,—In the abstract of my second Lettsomian Lecture, which you very kindly published in your issue of March 16th (p. 512), there are a few corrections I should like to make to avoid misunderstanding.

In paragraph 3 "undoubted syphilis" should read "untreated syphilis," and I did not say that in the period of freedom from symptoms the Wassermann was negative, but that it was less positive than in the active secondary stage, and might even become negative. In the last paragraph but one "continuous allergy" should read "cutaneous allergy." Lastly, my comparison between syphilis, tuberculosis, and rheumatic fever was quoted *in extenso* from a paper by Swift and his co-workers, to whom, of course, acknowledgement was made in my lecture.—I am, etc.,

London, W.1, March 15th. H. W. BARBER.

THE INTRACUTANEOUS TUBERCULIN TEST.

SIR,—Professor S. Lyle Cummins is hardly correct in stating (March 16th, p. 522) that, "so far as adults in this country are concerned, a positive tuberculin reaction has no diagnostic significance whatever." The Koch phenomenon, of which this test is but a modification, is, as Professor Cummins knows, long past the stage of scientific corroboration; and while it is true that its value in adults is limited, this is due, not to its lack of significance, but to its enormous significance—namely, wholesale infection. While no one familiar with the subject will initiate a long and expensive course of treatment by tuberculin on the strength of a positive intradermal test alone, there are other indications which may make it important to follow up the line of thought thus initiated.

The Medical Research Council has recently seen its way to recommend the intradermal tuberculin test for cattle (Special Report Series, 1925, 1928) as a reliable substitute for the more troublesome subcutaneous test as a means of differentiating sound and infected animals, and although one may not agree entirely with its conclusions, these are supported by a large volume of evidence.

The day is not far distant when greater value will be attached to the conception of a tubercle-free population than to that of tubercle-free cattle, and we are already becoming familiar with the word "detuberculization," which opens up an arresting vision.—I am, etc.,

Wandsworth, March 17th. ROBERT CARSWELL.

TUBERCULIN FOR ASTHMA IN CHILDREN.

SIR,—I was much interested by the paper on asthma in children by Drs. R. H. Simpson and Kenneth Stone, which appeared in the *Journal* of February 16th (p. 291).

What was more especially interesting to me was the fact that the authors use tuberculin in treatment with satisfactory results. As I have used tuberculin for some years in tuberculous asthma, perhaps I may be permitted to discuss the matter from the light of my own experience. I have dealt with the subject at some length in book form,[1] so I will only give a brief summary of the chief points bearing on the matter. I define tuberculous asthma as an "asthma occurring in a patient who reacts definitely to tuberculin or has *x*-ray or other evidence of tuberculosis, and in whom there is no discoverable cause beyond the tuberculous factor."

The following are the main characteristics of tuberculous asthmas:

1. They all react to tuberculin, but usually not very strongly.
2. The systolic blood pressure is a fairly good one, 120 to 140, not low, as one so often finds in tuberculosis.
3. The skiagraphic appearances of the lungs are normal in about 50 per cent. Of the remainder, only a small proportion show definite signs of activity.
4. The diurnal variations of temperature are usually very slight.
5. The season of the year has little influence.
6. With regard to food, they are not usually affected by meat, but they have a peculiar intolerance to fat and, to a lesser extent, to carbohydrates.
7. As to the age of onset, I have known it commence at the age of 4, but in other cases not till after 50.
8. A definite family history of asthma is rare, but a family history of tuberculosis is common.
9. The patients are often in poor health. They seem to be suffering from a mild form of toxaemia. This is in contrast with what one finds in many other forms of asthma.

H. Grossfeld of Vienna[1] considers that genuine cases of bronchial asthma are tuberculous. He also states that, in animals infected with human tuberculosis, asthma may be induced by injecting tuberculin. He thinks that asthma is a protective defence against tuberculous invasion.

While agreeing that the majority of cases of asthma are probably tuberculous, they are not *all* so affected, for, if they were, we should get a much higher proportion of cases reacting to tuberculin than we do. It is certainly a fact that an overdose of tuberculin in a tuberculous asthmatic will produce an attack of asthma. I also agree that in a sense tuberculous asthma may act as a defence against tuberculosis of the lungs. At any rate, it is comparatively rare to see asthma in an advanced stage of phthisis. But this is somewhat of a digression.

Having made a diagnosis on the aforementioned data, I commence treatment with 0.1 c.cm. of tuberculin liniment and double it each week till 1 c.cm. is given. When fairly big doses have been administered in this manner, a tuberculin rash very commonly appears on the arm or any other site where the liniment has been applied, and this is usually accompanied by an amelioration of the asthma. Should this not be the case, I proceed to injections, commencing with T.A.F. 0.0001 c.cm. and cautiously increase week by week. If these doses cause reactions or an attack of asthma, it is generally wisest to return to the liniment and continue with this till the patient is effectively desensitized.

I agree with Drs. Simpson and Stone that there is an "optimum" dose for each case, and it is unnecessary to increase beyond this dose. Having found the optimum dose, which is sometimes big, sometimes surprisingly small, I inject with it once a fortnight or at even less frequent intervals, and eventually discontinue altogether.

I have not found tuberculin of service in non-tuberculous asthmas. I treat these with peptone or autogenous vaccines and get a fair amount of success, especially if a focal infection has been found and dealt with. The success is, however, not to be compared with that which I have had with true tuberculous asthmas treated with tuberculin. Practically every case of tuberculous asthma is ameliorated if not cured. The general health improves, then the attacks of asthma get less severe, and eventually, in most cases, cease altogether.

The difference of opinion between myself and Drs. Simpson and Stone as to the specificity of tuberculin may be due to a difference in technique. As I have said, patients with tuberculous asthma are not, as a rule, very sensitive to tuberculin. The authors use the von Pirquet method; I use the modification of this practised by H. A. Ellis. The point about Ellis's method is that an incision is made through the von Pirquet droplet so as to draw blood. The test is, consequently, more delicate than the ordinary one, a point of considerable importance in diagnosing insensitive asthmas. Another point is that in treatment they use "old tuberculin," which contains albumose, whereas I use "tuberculin albumose free," in which the albumose has been removed, so far as possible, from the preparation. Is it not conceivable that the good results they are getting are due to the albumose? These are, however, minor points. The great thing is that they and some others are gradually realizing the value of tuberculin, which, even at the present time, to most of our profession, spells anathema.—I am, etc.,

London, E.C., Feb. 21st. F. E. GUNTER.

IMMEDIATE ENUCLEATION FOR QUINSY.

SIR,—As Mr. Vlasto would appear to be sceptical of the good result I obtained in the case quoted on February 23rd (p. 374), would you be good enough to allow me to reply to his queries under three headings?

1. Trismus, which is usually most noticeable in the region of the anterior pillar and due to the action of the superior

[1] *Tuberculin in Practice: Its Value in the Diagnosis and Treatment of Early Tuberculosis and Asthma.* Gregg Publishing Company. 1928.

[1] H. Grossfeld. Quoted in *Epitome* of the *British Medical Journal*, November 13th, 1926, para. 468.

constrictor muscle, is overcome not by a sedative, but by the action of the local anaesthetic. The sedative given is two cubes of sedobrol in a warm drink an hour or so before operation. The local anaesthesia is produced as follows. There is no preliminary swabbing of fauces or palate. Three drachms of 0.1 per cent. cocaine solution (1 grain to the ounce), to which 3 minims of 1/1000 adrenaline chloride solution have been added, are injected by a Matthew's syringe with curved needle—a drachm at a time, (*a*) just behind the anterior pillar, (*b*) just in front of the posterior pillar, and (*c*) behind the upper pole of the visible tonsil. There is a noticeable blanching and distension of the mucous membrane, but the injection is not resented by the patient.

2. The operation is proceeded with almost immediately. A short-bladed long-handled knife (Robertson pattern or Bard-Parker, blade No. 15, handle No. 5) is introduced at the base of the anterior pillar, and carried firmly upwards to the upper pole, following accurately the margin of the pillar, which is always clearly defined; the upper pole is encircled, and the knife carried downwards between the posterior pillar and the tonsil till it meets a tongue depressor provided with a flange, by which the left hand holds the tongue downwards and inwards. The tonsil is next drawn inwards and forwards by a Richards vulsellum, and the rest of the dissection of the tonsil completed by a long and curved pair of Mayo scissors in the manner described by Mr. Wallace. In a quinsy the tonsil is more friable than usual, the capsule having almost certainly been perforated in the course of the condition, and may consequently not be completely removed by the Tidding snare; this can be put right on a second inspection. The pus and blood are now carefully swabbed away by gentle pressure in the tonsillar bed. The patient already feels much relieved, and the pillars are relaxed. A pillar-retractor lays the tonsillar bed fully open to inspection, and the mouth is at once rinsed out with a suitable mouth-wash. No serious haemorrhage has so far been experienced.

3. The after-treatment is relatively simple. Frequent mouth-washes are employed for three or four days, or as long as may be deemed necessary. On the same evening the 0.1 per cent. cocaine solution may be safely sprayed on the fauces, or applied to the tonsil bed on a gauze pledget, and aspirin (10 grains) is sufficient to secure a fair night's rest.

Mr. Vlasto will probably agree that the usually accepted treatment of quinsies leaves much to be desired. Cases frequently reach hospital after one or more attempts at incision have been made and have failed. After healing has taken place the tonsil is rarely removed, and the patient is liable to recurrences. Removal of the tonsil removes the cause, just as extraction of a decayed tooth is usually all that is required in the treatment of a dental abscess.

Finally, two important criticisms have been, and will be, levied against this method. First, with regard to the use of cocaine: the very weak solution here employed is sufficient to produce analgesia, if not always complete anaesthesia, and at the same time a marked reduction of haemorrhage and a minimal risk of cocainism. Secondly, it may be considered unsurgical to produce a large raw surface in the presence of suppuration, but experience will show whether such a risk is not far out-balanced by the improvement in drainage, the earlier recovery of function, and the free access of antiseptics to the tonsil bed itself. I feel confident that those who employ this method in quinsies will be agreeably surprised, but they should practise the technique on simple cases first.—I am, etc.,

Oxford, March 11th. HUGH WHITELOCKE.

SIR,—Mr. Michael Vlasto (March 9th, p. 477) appears to have been using the razor edge of a fine technique for a surgical operation, which, comparatively speaking, needs a billhook and hoe.

The trismus yields even in the worst cases to the powerful leverage of the Sydenham gag, while the capsule is represented by the shaggy wall of the abscess cavity on its tonsillar aspect. Sometimes one undoubtedly removes quite an appreciable part of the anterior pillar and other tissues—for example, the ossified stylopharyngeus muscle and styloid process, broken off from the temporal bone, as in one case I reported (February 16th, p. 296), but the patients are all the better for the removal of such coccus-soaked fibrous scars.

The ultimate technique which will survive for use by the practitioner of the future must be one which is quick, easy, safe, and within the capacity of even a moderately clumsy operator, and whose complications permit the application of quick, easy, and safe remedies or preventive steps. The dangers I keep in mind, but have not yet met in 1,000 cases or more, are as follows:

1. Bleeding.—Immediate, reactionary, and secondary haemorrhage can be readily controlled by sharply jerking off with a Collins pile forceps every tag in the empty bed of the tonsil. The forceps are inserted open, with one oral fenestrated end pointing upwards under the supratonsillar fossa and the other as far as possible below the site recently occupied by the inferior pole, and are then closed, with the ends lightly pressing against the empty bed. Haemoplastic deficiency leading to continuous oozing can be treated by injecting, locally, fresh or "proprietary" serum. I have not tried this for quinsy cases, the first method having always proved adequate, but have used it for "bleeders" accidentally operated upon in routine clinic work by the blunt-bladed guillotine method. In these cases I have injected the palate and pillars, and also the retropharyngeal tissues, because oozing came from the post-nasal region as well.

2. Inhalation of clots or pus.—This can only be guarded against by placing the patient in a proper position. Induce anaesthesia with the head well raised on several pillows, and, when fully under, then the head must be absolutely over the end of the table and upside down, and the shoulders raised by a folded towel. Meanwhile the assistant or anaesthetist must be drilled to keep a good airway, by holding the tongue out with the clip and, most important of all, the mandible well forward. This prevents the laborious inhalations which might suck in such clots or pus; these can then fall into the roof of the mouth, whence by a flick of the fingers they may be swept out over the upper incisor teeth.

3. Dislodgement of septic clots into veins resulting in pyaemia.—This danger must be guarded against by avoiding pressure on the quinsy until the long Mayo scissors have opened the abscess. When, as in 20 per cent. of the cases, the condition is a pure streptococcal cellulitis with jelly-like oedema, the scissors can open widely behind the tonsil and scar tissue, and the finger follow to detach the upper pole and posterior pillar.

In one emergency case I enucleated both tonsils for quinsy with only a long artery forceps, a pair of domestic scissors, a safety-pin for a tongue clip, and two cotton reels for a gag. If anyone would care for a demonstration I should be pleased to arrange it, here or elsewhere.—I am, etc.,

Bishop's Stortford, March 11th. R. A. R. WALLACE.

THE CAUSE AND CURE OF MORNING SICKNESS.

SIR,—In his letter published on March 9th (p. 479) Dr. Reid inquires with regard to the recognized propensity of glycerin to cause abortion. I have never had such a case in my practice, and this extending over many years. I have had this same inquiry made by the matron of a nursing home in Glasgow, where the subject has aroused a good deal of criticism.

It is only fair to say that I am cognizant of two cases of abortion which have occurred in the practice of others. The first was one of a lady in Nottinghamshire on whom I had operated for a badly torn cervix with a good deal of prolapsus uteri. My treatment stopped the vomiting, but some time afterwards she aborted with a twin pregnancy. The other case was one which occurred in my son's practice. The treatment was given during July, 1928, and during August she was overworked in nursing two of her relatives. She aborted in September, 1928. My conviction is that in neither case was the glycerin responsible.—I am, etc.,

Paisley, March 9th. ANDREW RICHMOND, M.B., C.M.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Lords having returned the Local Government Bill with amendments, the Prime Minister announced that the House of Commons would consider these amendments on Friday, March 22nd. Among them was Lord Onslow's amendment providing for consultation between the new public health authorities and representatives of the local voluntary hospitals regarding the preparation of schemes for provision of hospitals and other institutional accommodation. The Minister of Health is understood to have ready, for dispatch to counties and county borough councils soon after the bill passes, a model administrative scheme under Clause 4 of the bill.

The Local Government (Scotland) Bill has passed second reading in the House of Lords.

This week the House of Commons further considered the Navy Estimates and debated general questions on the Consolidated Fund Bill.

The Local Government Bill.

Report Stage in the House of Lords.

On March 14th the House of Lords considered the Local Government Bill on report. Lord ONSLOW, who was in charge of the bill for the Government, moved a drafting amendment to Clause 2. He explained that this clause handed over to maternity and child welfare authorities functions under Part I of the Children Act, 1908, and converted functions relating to vaccination into public health functions. It was convenient that these two sets of functions should not be dealt with as transferred functions under Clause 4 of the bill. Similarly, the provisions of Part I of the bill, relating to acquisition of land and to accounts and audit, should not apply to them.

The House agreed with an amendment designed to make the changes Lord Onslow thought necessary.

Administrative Arrangements for Discharge of Functions Transferred to Councils.

Clause 4 enjoins the council of every county and county borough to prepare and submit to the Minister a scheme of the administrative arrangements to be made for discharging the functions transferred to the council under Part I of the Act. Lord COZENS-HARDY moved to add after the word "Act" "and any similar functions under any of the Acts set out in Clause 5." He said the explanatory memorandum accompanying the bill pointed out that the Poor Law administration would be transferred to authorities already providing hospitals "which overlap similar provision made by boards of guardians for persons who are destitute." The memorandum went on to say that, "The organization of the institutional service can only be undertaken by a body viewing the needs of the county as a whole." Lord Cozens-Hardy said a Minister could not judge whether a council had envisaged the whole problem when that Minister had only to deal with the discharge of the transferred Poor Law functions. The bill did not require the scheme to survey the whole area so as to set up administrative machinery which would secure the best use and development of existing institutions. Rationalization of the hospital services might call for the transfer of some functions from the Health Committee to the Public Assistance Committee, but the bill did not provide for that. Without freedom to redistribute functions between the old and new committees a council might find itself hampered in preparing a scheme which would dovetail Poor Law and public health functions into one whole. He had also put down to later clauses amendments designed to secure this, and he would like to make the same insertion into the new clause which Lord Onslow had put down concerning consultation with voluntary hospitals. The new clause meant that voluntary hospitals and the medical profession need only be consulted on a limited portion of the field. The new clause would leave the council free to provide extra hospital accommodation without any consultation if the proposed new institution was not required for Poor Law functions. If overlapping were to be prevented it was essential that the consultation should cover all hospitals, whether provided in discharge of the transferred functions or of similar functions under the Public Health Acts.

Lord ONSLOW said there was no need for the words which Lord Cozens-Hardy sought to add to the clause. Arrangements under the special Acts did not need to be included in the scheme. Where a declaration was made of intention to deal with the destitute under one or other of the special Acts (Public Health Act, Mental Deficiency Act, Maternity and Child Welfare Act, etc.) the result would only be to bring additional persons within a scheme which had in nearly every case been approved by the Minister of Health.

Lord Cozens-Hardy's amendment was negatived.

Consultation with Representatives of Voluntary Hospitals.

The new Clause 13, proposed by the Government while the bill was before the Lords in committee, and then inserted, ran:

"*Consultation by councils of counties and county boroughs with bodies representing voluntary hospitals.*—The council of every county and county borough shall make such arrangements as they think desirable for securing that the functions transferred to them under this part of this Act with respect to the provision of hospital accommodation will be discharged after consultation with such body, if any, within the county or county borough as they consider to represent the voluntary hospitals in the area."

Lord ONSLOW had an amendment to this on the paper.

Lord HANWORTH moved a revised form of the clause, which sought to provide that the persons consulted should include bodies or persons representing the voluntary hospitals of the area and representatives of the medical and surgical staffs of any voluntary hospitals in the area, and that the subjects of consultation should include hospital treatment as well as hospital accommodation. He said he had no right to speak for the hospitals, but intervened as a draftsman. Some very loose terms had been used when the subject of hospital accommodation was discussed in committee. His form of clause proposed to make the consultation compulsory, and to give the council freedom to consult those carrying on work in cottage hospitals who might not have an organization or a share in any committee. He thought the use of the word "accommodation" in the Government clause narrowed the consultation too much. He was sure that the peers had not intended to refer merely to the provision of beds, and he therefore put in the words "and treatment."

As a preliminary to discussion the House discarded Clause 13 in its original form. Lord READING then remarked that the discussion in committee had shown a consensus that specific provision should be made in the bill to ensure consultation with the voluntary hospitals. The Government proposed consultation, but the council would not be bound by anything which was urged by the voluntary hospitals. He approved that. He agreed with Lord Hanworth that it was desirable to specify treatment as well as accommodation. Lord Reading objected to the Government clause leaving to a council the power of determining what body, in its opinion, represented the voluntary hospitals. There might be a dispute in some county on whether a body of persons really represented the voluntary hospitals. Such a dispute ought not to be brought before a court of law, but referred to the Minister, whose decision should be final.

Lord KNUTSFORD urged the House to accept the word "treatment." For the benefit of the people at large he wanted the county councils, in drawing up and carrying out their schemes for new hospitals, to have the experience not only of laymen who had managed hospitals, but of the medical and surgical staff, who represented the highest advance and highest knowledge in the profession. At present the country had two diverse bodies—the voluntary hospital, with a magnificent staff, and the Poor Law infirmary, with perhaps one able man and no staff of importance to help him. No improvement could be carried out unless there was co-ordination and co-operation in working. He hoped that with such recurrent consultation with those at the head of the profession they would no longer see, as they now did in some of the Poor Law infirmaries, one man, however able, doing every sort of operation, as he would never dare do on the staff of a voluntary hospital. He hoped they would not continue to see anaesthetists employed who were nothing like so good as those available in the profession. He hoped they would never see what he saw last year—a young man, not even on the staff of a great hospital, going to take over the locum at one of the biggest Poor Law hospitals, first on the medical and then on the surgical side. That young man had said to Lord Knutsford, "Look at the experience for me." But what about the patients?

Lord BLEDISLOE feared that cottage hospitals might not be represented by the bodies or committees selected as representative of voluntary hospitals. The small village hospitals also served as clinics for examination and treatment, under the Education Act of 1921, of children suffering from small maladies of the throat, ear, or eye, and so justified themselves for county work.

Lord ONSLOW had on the paper the following proposed new clause in substitution for the Clause 13 which the House had just discarded:

"*Consultation as to the provision of hospital accommodation.*—The council of every county and county borough shall, before making provision for hospital accommodation in discharge of the functions transferred to them under this part of the Act, consult with such committee or other body, if any, as they consider to represent both the governing bodies and the medical and surgical staffs of the voluntary hospitals providing services in or for the benefit of the county or county borough."

Lord Dawson's Amendments.

Lord DAWSON OF PENN had handed in two amendments to Lord Hanworth's proposed clause. These provided that the council should also consult "with representatives of the medical faculty of any university which serves the area." He said he wished to point out the crucial differences between Lord Hanworth's clause

and that which Lord Onslow had placed on the paper. The House had agreed in committee that the new public health bodies were, at the moment they entered the field of curative medicine, going to undertake a large responsibility. Neither the councils nor the medical men advising them would have previous knowledge or experience adequate to carry on these new duties, and the sense of the House of Lords in committee had been that some help should be given, not by compulsion, but through conference with the voluntary hospitals and the staffs attached to them, and with that part of the medical profession which had always dealt with curative medicine. He had understood the committee to agree that this consultation should be real, effective, and recurring. The Government clause said there should be this consultation on hospital accommodation. In plain English "accommodation" meant nothing more than the mere fabric and arrangements of the buildings. That was a futile concession. If, on the other hand, the words "and treatment" were included, that did not mean that medical men and representatives of hospital managers were to come in every time to interfere with the proper management of these new hospitals. It meant that real conference should take place to determine not only the buildings to be put up, but the purposes for which they were to be used. He was not wedded to the words "and treatment," but he was to the principle that the people who had acquired experience through generations should bring it to the aid of these inexperienced councils and their medical men. The work of a general hospital had grown up through generations, and there was among members of the staff a tradition, a habit, an atmosphere of restraining opinion, which secured that, while every man got his chance, the right man was put on the right job. If a young and talented man showed a tendency to allow his enterprise to outstrip his judgement, Lord Knutsford, for instance, might step in with a word of restraint. The result was that wrong things were not done and the right men got the right jobs. The system had grown up little by little, with all the talent of the medical profession behind it. All men of talent moved in the direction of hospital work. Did the House wish to alienate the profession? How could they work the hospitals without it? He sometimes imagined that the Government wished to do it, because they brought in the bill without consulting the heads of the profession. Suppose an enterprising council said, with good intentions, that it would take up radium. All the medical profession asked, before these inexperienced councils took up a weapon so useful for the public good, so powerful in the right hands, so dangerous in the wrong, was that they should confer with persons of experience whether this treatment was to be used, and whether, when the treatment was complicated, it should be done in other places. An inexperienced hospital would require years to get the right staff, and could not get it unless the confidence of the profession was won. Until these new places had earned academic standing they would not draw the best men from the universities. About the founding of these new hospitals there had been no proper conference with the medical profession, however informal and unofficial. Surely it would have been natural to have called the heads of the profession together and to have said, "We think of giving powers of general treatment to these new county hospitals. Can you give us advice and draw up a scheme? We do not commit ourselves to accepting it." Because there had been no proper consultation of that sort he was sceptical when he found Lord Onslow's clause gave nothing but a barren concession on hospital accommodation, and contained no words which said the medical profession should be consulted on the purposes for which that accommodation was to be used.

Lord ONSLOW then offered an explanation of his alternative clause (set out above the commencement of Lord Dawson's speech). He said this was prepared to give effect to the desire Lord Dawson had expressed in committee, that there should be consultation with "any body existing in the area which is so constituted as to be representative of the duly qualified medical practitioners and of the medical and surgical staffs of the voluntary hospitals in the area." Lord Onslow remarked that Lord Dawson had not put those words on the paper, and that Lord Hanworth had thought they should be drawn tighter and made more explanatory. The Government had done something to meet that view. Turning to Lord Hanworth's amendment (summarized above), Lord Onslow said the Government could not agree to consultation with "persons" as well as with "bodies." That would enable a local authority to consult with individuals but refuse to consult with the Voluntary Hospitals Association or with the British Hospitals Association. It would enable a county council to "give the go-by" to hospital representatives. The Government thought the body to be consulted should represent the voluntary hospitals in the area, including the medical staffs. Till recently there existed, in practically every county and in many county boroughs, local voluntary hospital committees, formed by the Voluntary Hospitals Association. A number still existed, and were active. In Manchester and Sheffield good work was being carried on by these bodies. Some had become hospital councils, and some, especially in the county areas, existed on paper. Again, the Hospitals Association had a network of committees over the country. They were reorganizing these already to make more serviceable bodies, which would be at the disposal of the local authorities for the purposes mentioned in the bill.

Lord KNUTSFORD interposed to say there were no medical men on the Hospitals Association.

Lord ONSLOW replied that though there were none on the Hospitals Association there were on the voluntary hospitals committees. On these, medical men were represented both by consultants and by general practitioners connected with the hospitals. There might be areas where no committee was available at present, and in these it was desirable that one should be set up. As a result of the bill voluntary hospitals in each area should combine for the purpose of consulting with the local authority. Lord Knutsford assured him that the cottage hospitals, for which Lord Bledisloe had expressed concern, were represented on the Hospitals Association, and he had no doubt that they would have the opportunity of giving their advice. As the local authority was the body responsible for managing its institutions, it should judge, who really represented the voluntary hospitals, and with whom it should establish relations. Lord Hanworth had suggested that where two bodies claimed to represent the voluntary hospitals of the district the Minister should judge. To carry out this suggestion would be difficult. There might be a voluntary hospital committee functioning in an area and doing good work. On the other hand, the Hospitals Association might say, "Surely it is more convenient and better to have one organization between the country." That had already been urged. For the Minister to decide, meticulous local inquiry would be needed. Lord Onslow thought the House could trust the local authority not to use the bad committee rather than the good one. He was willing to meet Lord Hanworth's objections to the phrase "if any" in the Government's new clause. Turning to the proposal that consultation should be about "treatment" as well as about "accommodation," Lord Onslow remarked that if Lord Hanworth thought "accommodation" too narrow he himself thought "treatment" too vague. He was advised that if "treatment" were included a local authority would be under an obligation to consult the committee not only on the internal management of the hospital, but on the medical treatment of the patients. Lord Dawson had said that would be unacceptable. In these circumstances the Government could not accept the amendment proposed by Lord Hanworth.

Lord DAWSON asked whether Lord Onslow would accept the words "hospital accommodation and the functions to which that accommodation should be assigned." He meant no interference of any kind.

Lord ONSLOW said he thought the Government could accept the proposal in that form.

Lord DAWSON said he would like to consult Lord Reading and Lord Hanworth. If told the words he had just suggested were sound drafting he would accept them.

Lord ONSLOW said he and Lord Dawson were getting close together.

Lord HANWORTH said he must adhere to the words "and treatment."

Lord ONSLOW said he was advised by the Government draftsman that "and treatment" would include dealing with the individual patients. Equal facilities would doubtless be suggested for, or claimed by, the medical advisers of the local authorities. These would say, "You are consulted *in regard to* the treatment of patients in the *local authorities'* hospitals. We desire that our medical advisers should be consulted in regard to the management or treatment of patients in the voluntary hospitals." That would not be desirable, and Lord Onslow said he was willing to accept Lord Dawson's new suggestion, which would meet the case. The new experimental system was interesting and important, and ought to be initiated with the good will of all local authorities. He had reason to suppose that this good will would be forthcoming, and that the arrangement would develop into a useful method of consultation between two great authorities dealing with the same subject.

Lord BEAUCHAMP pointed out that in the Local Government (Scotland) Bill "hospital facilities" included "arrangements with respect to the provision of treatment." English hospitals should be treated as well as Scottish hospitals, and the Lords should insist *on including* the word "treatment" in the English bill.

Lord COZENS-HARDY pointed out that Lord Onslow's amendment referred to "voluntary hospitals providing services in or for the benefit of the county or county borough." That met the case of the hospital *serving an area* though not within it.

Lord ATKIN said he could not imagine anything more objectionable than that the medical men in charge of a hospital should have to consult some outside body to determine what treatment they *should render* at a particular time to a particular patient. It did not seem to him that the words suggested by Lord Hanworth could bear that meaning. Treatment could only be in respect of general provisions.

The Lord CHANCELLOR said that if the bill provided that the council must consult with a body which represented the voluntary hospitals, then, when the council proposed to spend money on a scheme, it would be open to anyone to move for a writ of

hibition on the ground that they had not carried out the obligation imposed on them under the clause. If they had consulted with some body which, in the opinion of the court, was not a representative body, then they would not have carried out their duty. There would be more chance of advice being accepted if the persons whom the county council consulted were not forced upon them against their will. The wisest plan would be to let the county council consult those whom it regarded as representative of the voluntary hospitals in the area. Turning to the interpretation of "treatment," the Lord Chancellor remarked that Lord Dawson and Lord Onslow agreed that consultation should extend to the function for which the particular hospital was to be used. If that were so, the Peers would be wise not to insist on putting in words which the Government believed would have an undesired effect. He suggested that the House should accept the clause proposed by Lord Onslow on the understanding that before third reading the Government, in discussion with Lord Dawson, would endeavour to find words providing for consultation on the function for which the accommodation was to be assigned, but not open to the risk of bringing interference with detailed treatment.

The House then divided, and negatived Lord Hanworth's proposed clause by 52 to 42.

Lord ONSLOW then moved his new clause as set out above.

Lord DAWSON moved to amend the clause by adding provisos for consultation also with "the medical faculty of any university which serves the area" and with "the duly qualified medical practitioners in the area." He said the custom had arisen in late years of linking up medical services in voluntary hospitals with the medical faculties of the nearest universities. Representatives of the faculty of medicine who were concerned with laboratory investigations and forms of research should be able to join in any representations made in conferences with the local council. Liverpool University, for instance, by means of its medical faculty, spread its influence over seven or eight counties. Hospitals in all that area turned to it for advice and made use of its laboratories and teachers. Representation of the medical faculty of a university need not be confined to one county. Cambridge, Birmingham, Liverpool, and Manchester served large areas. His second proposal, for representation of the duly qualified medical practitioners in the area, he had raised in the debate on the committee stage. The House should bear in mind that the doctors who up to now had given their advice, which was excellent, because they were admirable in their own domain of preventive medicine, were much fewer than the 28,000 doctors engaged in curative medicine in England and Wales. When curative functions were going to be added to the county councils there should be some representation of the men who spent their lives dealing with disease.

Lord ONSLOW said the Government could not accept Lord Dawson's amendment. The point about representation of the medical faculties of universities was already met by the Government provision for consultation with representatives of the medical and surgical staffs of voluntary hospitals. If the university medical men did not usually attend the hospitals, then those medical men who were attached to the hospitals should be consulted by the councils. Those whose advice the Government desired were those who were intimately connected with the voluntary hospitals administratively, financially, or in a professional capacity.

Lord DAWSON intervened to remark that pathologists, bacteriologists, and those who did chemical and radiological work were not necessarily on the staffs of voluntary hospitals nor connected with the wards and the actual treatment of patients.

Lord ONSLOW said these men were connected with the hospitals in other ways, and their case might be met by the clause. Turning to the second part of Lord Dawson's amendment, Lord Onslow contended that to bring in medical men who were not connected with the hospitals but practised in the area would lead to confusion. It was undesirable that those who were unconnected with the hospitals should be brought in to manage them. Medical men connected with the hospitals would be amply able to supply the advice which the councils would seek.

Lord Dawson's amendment to Lord Onslow's proposed new clause was then negatived without a division, and Lord Onslow's clause was agreed to, after the words "if any" had been deleted on the motion of Lord Reading.

Recovery of Expenses for Maintenance.

Clause 16 (previously numbered as Clause 15), dealing with recovery of expenses from patients in council hospitals, does not allow expenses to be claimed from patients suffering from infectious disease.

Lord ARNOLD moved an amendment to ascertain whether surgical tuberculosis was covered by the words "infectious disease." He also contended that every encouragement should be given to persons suffering from cancer to seek treatment, and proposed that the Minister should have power to exempt from charges sufferers from such diseases as he thought fit.

Lord ONSLOW said the point had been considered, but the Government could not meet Lord Arnold's wishes. An infectious disease was one from which it was desirable to safeguard other persons. Cancer was not considered an infectious disease, and could not be included. Some forms of surgical tuberculosis were not included. The proper course was to lay down a criterion which would safeguard other persons, leaving the local authority to decide what was an infectious disease and what was not. That could not be closely laid down in the bill because, as Lord Dawson had pointed out, knowledge was changing from month to month. Diseases later found to be infectious would automatically come under the scope of the bill.

Lord Arnold's amendment was negatived.

Supervision of Midwives.

Clause 60 deals with the supervision of midwives, and enacts that any district council which has established a maternity and child welfare committee, and which employs a whole-time medical officer, may apply to be the local supervising authority under the Midwives Acts.

Lord HUNSDON moved to confine this privilege to councils which were also local education authorities. His object was to reduce the number of small districts which could apply for the inspection of midwives. He remarked that he was glad the Government, in response to representations in committee, had agreed to provide a local inquiry into these applications by district councils.

Lord ONSLOW said there were 139 district councils covered by the clause, and of them all but 52 were education authorities. Only six or seven large authorities did not happen to be education authorities.

Lord HUNSDON withdrew his amendment, and the House, on the motion of Lord ONSLOW, inserted amendments providing that the supervision of midwives should only be delegated by the Minister after consultation with the county council, and that if requested by the county council the Minister shall hold a local inquiry before making an order.

In Clause 129 (definitions) the following was added:

Page 111, line 10, at end insert ("'Public health services' includes services relating to maternity and child welfare, lunacy and mental deficiency, and the welfare of the blind").

The word "sanatoria" as used in the bill was supplemented by "or other institutions for the treatment of tuberculosis."

The report stage then concluded.

Local Government (Scotland) Bill.

On March 5th the Local Government (Scotland) Bill was considered on report, having previously been amended in committee of the House of Commons.

A new clause was moved on behalf of the Labour party by Mr. Johnston, the purpose of which was to empower the Secretary of State to raise to the status of a large borough, independent of the county, any borough which during the summer months habitually had a large excess of population.

Dr. ELLIOT said that Mr. Johnston had not made out a case; any argument had really been met when the Secretary for Scotland decided to leave the services of water, of drainage, and of sanitation within the purview of all boroughs. It was not considered that a fluctuating population required special provision to be made for poor relief, for lunacy, and mental deficiency. Dr. Elliot said that in small boroughs certain things were done counter to the interests of economy and efficiency. The northern district of Ayrshire had six small boroughs with six infectious disease hospitals averaging fourteen beds each. The object of efficient service would be better secured by a combination which would enable full use to be made of each of these institutions. Three or four years ago a part of the Springvale Hospital belonging to Ardrossan and Saltcoats was destroyed by fire; this was an opportunity for combination with Irvine, but the two boroughs preferred to re-establish the building which had been destroyed. The Government's proposal to make 20,000 population the lower limit for autonomous boroughs was not a temporary adjustment, but an attempt to make a strong financial unit which could put to fullest use existing institutional accommodation and plan its policy over a period of years.

Mr. JOHNSTON protested that the overwhelming majority of the boroughs in Scotland had, when profitable, combined to run joint infectious disease hospitals.

Dr. DRUMMOND SHIELS recalled that in a previous discussion on the same subject the Government had agreed to allow a medical officer to be retained in boroughs whose population was greatly increased during the holiday season. He remarked that boroughs like Oban and St. Andrews had supplied not only their own health services, but the health services for the county and hospital accommodation as well. He thought there was a case for such boroughs retaining their medical officer of health and their control over major health functions.

The clause was rejected by 205 to 115.

On Clause 2, dealing with the transfer of functions of town councils to county councils, Dr. ELLIOT said that the merging of local and county administrations would provide a more efficient service throughout Scotland. Committee after committee had urgently reported that wider areas of health services would be

for the good of Scotland as a whole. With regard to the Highlands and Islands, an authoritative committee, presided over by the Duchess of Atholl, and including Dr. Donald Murray, former member for the Western Isles, had recommended that for the major health services the area of administration in the Highlands and Islands should be the county. The clause was added to the bill by 181 to 93.

Consideration of the bill on report was resumed on March 6th, when Mr. JAMES STUART moved an amendment to delete some of the proposals of Clause 10, dealing with the uniting of boroughs and combining of councils for certain purposes. He suggested that in the case of the counties of Moray and Nairn it was not necessary to amalgamate public health services, because these had been adequately maintained in the past; both the county and the borough of Nairn were served by a voluntary hospital and district nursing services which were not a burden on the rates. In connexion with maternity and child welfare, there was an arrangement with local doctors to attend when children were ill. Although there was no formal scheme for tuberculous cases, adequate provision was made in this respect.

Sir JOHN GILMOUR said the county of Nairn, including the borough, had only a population of 8,790, and the county of Kinross one of 7,963. The Scottish Office desired to combine these two very small counties with their neighbours. Under the national health insurance scheme Nairn and Moray had been combined. Nairn had no county scheme for the treatment of tuberculosis, and none for maternity and child welfare service. Health services which were essentially necessary did not at present exist there. The medical officer of health and the school medical officer were obtained by combination with Moray. There were a considerable number of cases of tuberculosis in the county and borough of Nairn, and no institution existed for the treatment of early or advanced cases. The provision for school health administration was incomplete in Nairn, especially as regards dental treatment and treatment of the ear, nose, and throat. The Government's proposals for combination were accepted by the House by 157 votes to 106.

On Clause 33, which empowers the medical officer of health and sanitary inspector to act for small boroughs, Dr. ELLIOT moved to insert a provision that:

Except with the sanction of the Department of Health no person shall, after the commencement of this Act, be appointed sanitary inspector of a county or borough unless he possesses such qualifications as may be prescribed by the Department of Health.

He said the Government required to reserve the right to take further steps to raise the status of sanitary inspectors. The House agreed to the amendment.

Dr. ELLIOT moved a new clause dealing with the power of councils to expend money on public health propaganda. It ran:

It shall be lawful for any county council or for the town council of a large borough to incur expenditure in making contributions to the central council or committee of an organization approved by the Department of Health, which provides services of the nature of publicity or educational propaganda for any purpose relating to public health, or in the provision by themselves of such services.

Dr. Elliot said the clause was put down in consequence of a discussion in committee about the power of local authorities to spend money on propaganda against venereal disease. He had then agreed to go into the matter again on the understanding that any proposals would not deal solely with that disease, but that general powers would be given for propaganda in respect of health education concerning any kind of disease. This new clause met that undertaking, and he understood it was particularly desired by the city of Edinburgh.

Dr. DRUMMOND SHIELS was glad of the new clause as far as it went. He would have preferred some national effort, either by the Department of Health or by some central organization, whereby national propaganda would have been effectively carried out. It was not certain that dependence on the efforts of local authorities in this matter would be satisfactory. It was right that propaganda should not be confined to any disease. For example, if public health propaganda on the importance of the early treatment of cancer were carried out many lives would be saved. The concession established the principle that health propaganda was the duty of public authorities.

The clause was added to the bill, as was also another clause moved by Dr. Elliot to sweep away the disqualification whereby sick persons in Poor Law institutions were only allowed to receive pensions up to a period of three months' residence.

The report stage then closed and the bill was set down for third reading on March 11th.

Third Reading Debate.

On March 11th Sir JOHN GILMOUR moved the third reading of the Local Government (Scotland) Bill. He said that with the best intentions many of the existing local authorities had been incapable of meeting adequately the problems connected with housing and public health matters. Unless there was a co-ordination of effort there would be wastage and inefficiency. In Glasgow, for example, he did not see that co-ordination and co-operation between either the private hospitals or the private hospitals and the public hospitals which was essential if there was to be real efficiency. The provisions of the bill held out, not only the hope but, in his judgement, the certainty of a great solution of the problem. They had behind them the whole-hearted co-operation of the managers of the great hospitals and of the members of the medical profession, who were closely linked with them. In the development of these services he visualized more and more paying wards within the hospitals and the building of annexes in the fresher and purer air of the countryside, to which would be taken at various stages those who first entered the hospitals in the great cities. It was only by complete co-ordination between the work in the city and the local authorities in the counties outside that they would get a proper solution of this problem. If the bill had dealt with no other problem than the improvement and co-ordination of the medical services he would have been proud to have introduced it.

Mr. JOHNSTON, in moving the rejection of the bill, said that it was with genuine regret that they saw in the measure the disappearance of a training ground for public administration in the form of the small burghs of Scotland. He hoped that it would be explained in Scotland that the Government were giving no relief for hospitals, but were giving relief for distilleries; that venereal disease would be free, but that maternity treatment would be charged for; and that if an old man who was treated for bronchitis could not pay, his son or daughter could be called on to pay, or, if they could not pay, then his grandson or granddaughter could be called on to pay.

Dr. DRUMMOND SHIELS seconded the rejection of the bill. He denied that the change from the percentage grant system to the block grant system was a step forward in regard to the public health services. He could not, he said, get away from the fact that the impulse for this change came from the Treasury, and not from any medical or local government source. Any saving to the Treasury in public health development meant heavier local burdens on depleted resources. That was one of the bad things in the bill, and even child welfare and maternity could not be saved from it. He was more hopeful about the hospital sections of the bill than any other part. The changes that had been made during the committee stage, although by no means all that they could have wished, had made some progress possible. The distinction between infectious and other diseases could not be justified, and they could only hope that the local authorities would use their discretion wisely in exercising their powers to enforce payment. Many of the people requiring treatment were already harassed by rent and other obligations; they needed more money when they were ill rather than to incur new penalities. He regretted especially in this connexion that the Government had not seen their way to exclude maternity hospitals. Presumably there would be paying and non-paying wards in the municipal hospitals, just as there were already in many voluntary hospitals. The voluntary hospitals had reluctantly agreed to the new arrangements, but some of their managers and supporters, and certain eminent members of the medical profession, had been voicing their fears of extinction by the municipal hospitals. No one would deny the splendid work which had been done, and was still being done, by the voluntary hospitals. If it was looked at rightly the new development was not a censure on voluntary hospitals, but was a real triumph for their educational work. They had convinced the community that medical and surgical aid must be promptly and fully available to every member of the population. The voluntary system, admittedly, could not achieve this, and the community, therefore, must accept the responsibility. For many years to come there would be need of all the resources of both voluntary and municipal hospitals, as there was a very big leeway to make up; and even if municipal general hospitals ultimately met a large part of the demand, there was still abundant pioneer work for voluntarism to do. The public conscience was still dull in regard to crippled children, for example, 75 per cent. of whom could be made self-supporting if they were treated earlier. Yet they were languishing in cripple hospitals and private homes throughout the country, a burden and an unhappiness to themselves, and very often a burden on the community. Mental defectives were still largely untouched by any kind of organization. Rheumatic children, who became very often permanent invalids, were, in many cases, without treatment of any kind or any opportunity of getting it. It was well known that the blind and deaf were also a class who had not yet received the attention which their condition and need merited. He hoped, therefore, that no dog-in-the-manger policy would attempt to hamper the new municipal and county efforts to do the barest duty to the community. There were difficulties in regard to the co-operation of the voluntary and municipal hospitals—in regard to staff, medical teaching, and many other matters—but they could be surmounted by a spirit of goodwill, which, he trusted, would be forthcoming.

Dr. ELLIOT, replying to the debate, pointed out that he had as much knowledge perhaps of hospitals and waiting-lists as almost any other member of the House. He had had the compiling of these waiting-lists. He had realized the hope deferred that made

the heart sick as week after week and month after month cases would come up asking for treatment when they knew that treatment would be an advantage, but owing to the shortage of accommodation they were forced to deny it. They were going a great way to remedy that in the proposals in the bill. The Mackenzie Committee reported that 700 beds of the first class could be made immediately available if agreement were reached between the municipal and Poor Law authorities and the voluntary hospitals, and that it would be possible to bring hundreds of beds immediately into service in Glasgow alone. In Aberdeen it had been possible to bring 160 beds into operation and keep them constantly filled. They could do that, and more, in the other cities under the hospital clause in the bill. The bill was read a third time by 269 votes to 86.

On March 12th the bill was introduced into the House of Lords and read a first time.

On March 19th, in the House of Lords, the EARL OF AIRLIE moved the second reading of the Local Government (Scotland) Bill. He said its principal purpose was the provision of adequate areas for carrying out the major local government services with a single controlling authority. EARL BEAUCHAMP moved the rejection of the bill, and expressed regret at the disappearance in so many cases of the *ad hoc* authorities. There would be a large increase in bureaucracy, and much of the splendid work done voluntarily in Scotland would disappear. Lord PARMOOR said that the bill, in respect of matters such as the recovery of expenses of the treatment of the sick, was a great improvement on the English bill. The MARQUESS OF SALISBURY said that if the tendency of the bill, as had been suggested during the debate, was to increase bureaucracy, he would profoundly regret it, and the Government would give consideration to amendments designed to prevent such a result. The bill had been accepted in the country as a great measure of reform. The motion for the rejection of the bill was defeated by 66 votes to 22, and the bill read a second time.

Research on Influenza.—Mr. A. M. SAMUEL, replying on March 12th to Mr. Malone, who asked if the Chancellor of the Exchequer would consider making a grant to the Medical Research Council or any other body for the purpose of research into the pathology of influenza, said that an inclusive grant in aid was made each year to the Council from the vote for scientific investigation. The Council had discretion to allocate any part of the grant to the purpose suggested by Mr. Malone if it should think fit. Mr. Malone asked if Mr. Samuel was not aware of the high death rate due to this malady in the last few months, and the apparent inability of the medical profession to deal with it. He asked whether the Government had not some responsibility to see that this research was carried out. Mr. Samuel replied that such a question specifically dealing with it should be addressed to the Minister of Health.

Notes in Brief.

Since January 1st, 1925, 58 slum clearance schemes have been confirmed by the Ministry of Health.

The Services.

OPERATIONS IN IRAQ.

THE name of Squadron Leader Hugh Leonard Burton, M.B., is among those brought to notice by Air Vice-Marshal Sir Edward L. Ellington, Air Officer Commanding British Forces in Iraq, for distinguished services rendered in connexion with the operations against the Akhwan in the Southern Desert, Iraq, during November, 1927–May, 1928.

ROYAL NAVY MEDICAL CLUB.

THE annual dinner of the Royal Navy Medical Club will take place this year at the Trocadero Restaurant, Piccadilly Circus, on Thursday, April 25th, at 7.30 for 8 p.m. Members who wish to be present are asked to inform the Honorary Secretary, Royal Navy Medical Club, Queen Anne's Chambers, Tothill Street, S.W.1, not later than seven clear days before that date.

DEATHS IN THE SERVICES.

Colonel William Frederick Ruttledge, R.A.M.C.(ret.), died at Farnborough on February 16th, aged 80. He was born on May 1st, 1838, and entered the army as assistant surgeon on March 31st, 1865. As a regimental officer he served in the 5th Foot, the Northumberland Fusiliers. He became surgeon major after twelve years' service, and retired, with an honorary step as brigade surgeon, on April 29th, 1885. After retirement he was employed in the Military Prison Department at Aldershot, and was given the honorary rank of colonel on October 18th, 1902, for services in England during the South African war. He served in the Afghan war of 1878–80, receiving a medal.

Major Charles James Addison, R.A.M.C.(ret.), died of pneumonia in London on February 21st, aged 74. He was born at Wyke Regis, Weymouth, on March 17th, 1854, educated at St. Thomas's and in the Edinburgh Extramural School, and took the L.R.C.P. and S.Ed. and the L.S.A. in 1880. He entered the army as surgeon on February 5th, 1881, became surgeon major after twelve years' service, and retired with a gratuity on November 28th, 1900. He served in the Egyptian war of 1882 (medal and Khedive's bronze star); in the Tirah campaign on the north-west frontier of India in 1897–98 (medal with three clasps); in the South African war in 1899–1900 (medal and clasp); and in the recent great war of 1914–18 (General Service Medal and Mercantile Marine Medal).

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on March 9th the degree of Sc.D. was conferred on Edward Hindle, M.A., Ph.D., Beit Memorial Research Fellow in Tropical Medicine, formerly Professor of Biology in the School of Medicine, Cairo.

UNIVERSITY OF LONDON.

PARLIAMENTARY REPRESENTATION.

SOME members of the executive of the University of London Conservative and Unionist Association, including Sir Philip Magnus, Dr. Sidney Phillips, and Professor W. E. Dixon, M.D., have intimated their intention of supporting the re-election of the sitting member, Dr. E. Graham Little (Independent Conservative).

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

AT the spring commencements, Hilary term, held on March 16th, the following degrees and licences were conferred:

LICENCE IN [illegible]. Dundon.
M.B., B.CH. F. R. Falkiner,
E. C. Hi
M.D.—T. J. Kelly.

NATIONAL UNIVERSITY OF IRELAND.

THE Senate, at its meeting on March 15th, recorded its deep regret at the death of Sir Bertram C. A. Windle, who, as Vice-Chancellor of the University and its representative on the General Medical Council and other public bodies, rendered invaluable and unfailing service to the advancement of the University, and expressed its sincere sympathy with Lady Windle and other members of the family in their bereavement. The Senate also adopted a resolution deploring the loss sustained by the death of Dr. Andrew R. J. Dungan, lecturer in medical jurisprudence, University College, Dublin, and tendered its sympathy with the relatives.

Professor David T. Barry, M.D., has been appointed one of the representatives of the University at the seventh centenary celebrations of the University of Toulouse in June next, and Professor W. D. O'Kelly, M.D., will represent the University at the Royal Sanitary Institute Congress to be held in Sheffield in July.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on March 14th, when the President, Sir Berkeley Moynihan, Bt., was in the chair. The Council offered its congratulations to the President on his elevation to the peerage.

The Diploma of Fellowship was granted to Ian Douglas Miller and the Diploma of Membership to W. F. Skaife, these candidates having complied with the regulations.

The following diplomas were conferred jointly with the Royal College of Physicians:

TROPICAL MEDICINE AND HYGIENE.—K. P. Anklesaria, F. C. K. Austin, [illegible] Bandyopadhyay, S. Batchelor, P. S. Bell, [illegible] own, J. Bryant, J. A. Carman, [illegible] L. S. Chatterji, N. Chilton, [illegible] Cook, M. Das, P. T. J. Doss, A. N. Duggal, D. P. Dutta, J. G. Green, H. E. Hargreaves, E. Haworth, [illegible] chorn, Y. M. Khan, C. E. M. J. [illegible] W. S. Nealor, S. L. Rikhye, [illegible] anford, Eileen M. Turner, [illegible] J. B. A. Wigmore, A. J. W. [illegible] Wilson.

OPHTHALMIC MEDICINE AND SURGERY.—S. Anneswami, Y. P. Ledl. [illegible] W. [illegible] on, S. J. A. Laubscher, A. A. El M. Magrabi, Sigrid L. S. Pearson, F. E. Preston, Gertrude E. Pugmire, B. W. Ryecroft, A. E. M. Soliman, A. D. C. Stoute, Annie V. Taylor, Marjorie P. Taylor, G. Vaishnavi.

Licences in dental surgery were granted to 31 candidates.

The President presented to the College a copy of a portrait of Ambroise Paré in the museum at Fécamp in Normandy, thought to be the work either of Mirvelt or Heufchatel.

It was decided to offer to hold a reception at the College in the evening of Tuesday, May 7th, for members attending the fifth International Congress of Military Medicine and Pharmacy.

The Secretary reported that the application for a licence from the Board of Trade for a British College of Obstetricians and Gynaecologists would be heard by the Board on March 22nd, and that the Royal College of Physicians of London and the Royal College of Surgeons of England would be represented by counsel in opposing the application.

Obituary.

WILLIAM WRANGHAM, M.D., M.R.C.P.,

Senior Physician, Royal Infirmary, Bradford.

ON March 16th Dr. William Wrangham, one of the best-known consultants in Bradford, died with startling suddenness from angina pectoris.

Son of the late Dr. Wrangham, William Wrangham was born in 1871 in Lincoln, where his family had lived for many generations, several members of each generation belonging to the medical profession. Having received his medical education at St. Bartholomew's Hospital he qualified M.R.C.S., L.R.C.P. in 1896, graduating M.B. in the same year, and proceeding M.D.Lond. in 1900. During the three years immediately following his qualification he held various resident appointments, and in 1900 he settled in general practice in Bradford, where shortly afterwards he was appointed chief police surgeon, assistant honorary physician to the Bradford Royal Infirmary, and assistant surgeon to the Bradford Royal Eye and Ear Hospital; at the time of his death he was senior honorary physician to the Bradford Royal Infirmary. In 1915, when St. Luke's Hospital was equipped as a war hospital, William Wrangham was placed in charge, with the rank of lieutenant-colonel. In this capacity he served until the hospital was handed back to the civil authorities in 1919, receiving in recognition of his services the Order of the British Empire, and letters of congratulation from the general commanding the Northern Division and Sir Berkeley Moynihan. When, in the following year, St. Luke's Hospital was taken over by the municipality, he was appointed senior honorary physician, and, relinquishing general practice, devoted himself entirely to consulting work, in which he was engaged up to the time of his death. In 1924, when the British Medical Association held its Annual Meeting in Bradford, he was honorary secretary of the Section of Medicine, and in the period 1927–28 he was chairman of the Bradford Division.

William Wrangham was not only a skilful physician, sound in diagnosis and prognosis, and resourceful in treatment, but a man of the highest probity, who was universally honoured by his medical colleagues and the many citizens of Bradford with whom his appointments brought him in contact. He is survived by his wife and two daughters, to whom and to his brother, Dr. J. M. Wrangham of Ripponden, we extend deepest sympathy.

WE regret to announce the death, on March 16th, after a brief illness, of Dr. WALTER JAGGER, one of the leading practitioners in the West End of London. He was born in 1871, and went from Shrewsbury School to study medicine at Edinburgh, graduating M.B., C.M. in 1896. He served in the R.A.M.C. throughout the South African war, and received the Queen's medal with four clasps and the King's medal with two clasps. After leaving the army he practised first in Lincoln, then at Bourne End, Bucks, and for the past fifteen years in London, where he held a number of clinical appointments. During the late war he was on the staff of Princess Christian's Hospital for Officers, and the R.A.F. Hospitals for Officers in Eaton Square and Bryanston Square. With Sir Henry Simson he attended H.R.H. the Duchess of York at the birth of Princess Elizabeth, and he was also in attendance on the Duchess during her recent attack of influenza. Sir Henry Simson writes: Memories going back to the time when we were students together in Edinburgh crowd in upon one when one thinks of Walter Jagger: his happy greetings, his quaint humour, and his old-fashioned courtesy and precision of manner. Nothing was too trifling in order that the thing to be done should be done properly. Whether in the lecture room, at the Students' Union, on the golf course, it was the same—something to be done, a proper way to do it, and always a happy faculty of seeing the humorous side of a situation. I have a suspicion that his service with the R.A.M.C. in South Africa was one of the happiest times of his life. It certainly left its impression on his character in after-life; but he never talked much about it, and it was not until years later, when he came to London, that we renewed the friendship begun in Edinburgh. We were associated very closely as secretaries of the Edinburgh University Club of London, and he gained a considerable reputation for making after-dinner speeches at the club dinners. His friendship was not given easily, but once gained he never let you down.

Dr. ELSIE THOMSON, who died at Kew on March 6th, was the younger daughter of Dr. T. C. Thomson, lately of the Colonial Medical Service at Hong-Kong. She was educated at St. George's School, Edinburgh, and after qualifying as a nurse at the Royal Infirmary, she graduated M.B., Ch.B.Ed. in 1923. Four years later she obtained the D.P.H. She was for some time resident medical officer at the Mothers' Hospital, Clapton, and later gained experience in public health work at Ilford, and under the London and Staffordshire county councils. In 1925 she was appointed assistant medical officer in charge of maternity and child welfare for the borough of East Ham, and retained this post until her death at the untimely age of 37. Elsie Thomson possessed qualities of mind and character that endeared her to all those who knew her. The following is quoted from an appreciation by Dr. Benton, medical officer of health for East Ham: "With the passing of Dr. Elsie Thomson the Public Health Department of East Ham has lost a loyal colleague, and the East Ham Corporation one of their most capable and valued officers. Her sweet personality and patient sympathy with those in difficulties won complete confidence. This has been many times emphasized lately by repeated inquiries from numerous mothers regarding the doctor's health and return to work." The mayor of East Ham attended the funeral at Richmond in his official capacity, accompanied by several representatives of the public health life of the borough.

The following well-known foreign medical men have recently died: Dr. MARCEL LERMOYEZ, an eminent Paris laryngologist, member of the Académie de Médecine, and one of the founders of the *Presse Médicale*, aged 70; Dr. FRÉBAULT, honorary professor of toxicology in the Toulouse faculty of medicine; Dr. RAPHAEL DUBOIS, honorary professor of physiology in the Lyons faculty of medicine; Professor GHERARDO FERRERI, director of the oto-rhino-laryngological clinic of Rome; Professor ALDO PERRONCITO, director of the institute of general pathology at Pavia; and Professor FILIPPO SPECIALE CIRINCIONE, director of the ophthalmological clinic at Turin.

Professor H. R. Kenwood writes: There are many readers of the *British Medical Journal* who will feel a keen sense of regret and of loss on hearing of the recent death of Mr. F. T. MARCHANT at the early age of 49. For thirty-five years he was a highly valued associate of mine in the Public Health Department of University College, London, where he came in contact with a very large number of medical men and women during their training for the D.P.H. He began his work at the College, at the age of 14, as a laboratory attendant; when he ended it he was a member of the College staff, a demonstrator and lecturer of rare ability, and the joint author of a textbook upon hygiene and public health (Jameson and Marchant). He acquired such a good knowledge and technique, both of public health chemistry and bacteriology, and he possessed such a wonderful power of informing and training others, that his services became invaluable. Indeed, his death will deprive the new London School of Hygiene (to the staff of which he had been elected) of one whose special experience and knowledge it will be difficult to replace. His great gifts won for him the esteem, and his good personal qualities the affection, of those who worked with him. Always kindly and sympathetic to those in difficulties, he was almost prodigal with the time and trouble he would devote to assisting them. This generous trait, and his modest, kindly, and unselfish disposition, will be held in tender remembrance by all his associates and by very many who are now medical officials in the public health services of Great Britain and her Dominions. Marchant was a man of poor physique, but the indifferent health by which he was often handicapped levied little toll of his mental energy. He made time for some useful items of research, and in his leisure he was a great reader and student to the end. He was "a home bird"—a fact which will not surprise anyone who knew something of his home life, for it was a very attractive home, if only from the standpoint of the great comradeship and devotion of the two who shared it; and our deepest sympathy will go out to Mrs. Marchant in her bereavement. There was no child of the marriage.

Medical News.

MR. CHARLES HERBERT HAMPSHIRE, M.B., B.S., B.Sc., F.I.C., has been appointed by the General Medical Council to be the secretary of the Pharmacopoeia Commission. He will take up his duties from June 1st. All communications intended for the Pharmacopoeia Commission should be addressed to the secretary of that body at 44, Hallam Street, Portland Place, W.1, and not to any individual.

A SPECIAL discussion on encephalomyelitis of man and animals will take place at a joint meeting of the Sections of Comparative Medicine and of Neurology of the Royal Society of Medicine on Wednesday next, March 27th, at 5 p.m. Mr. I. A. Galloway will open the discussion on behalf of comparative medicine, and Dr. J. G. Greenfield for neurology.

A COMPLIMENTARY dinner to the honorary medical board of the institution will be given by the Trustees of Lord Mayor Treloar Cripples' Hospital and College on Friday, April 5th, at Barbers' Hall.

THE Fellowship of Medicine announces that the first course in April will begin on the 8th; it will be a practitioners' course in medicine and surgery at the London Temperance Hospital, from 4 to 5.30 p.m. daily, lasting for two weeks. The London School of Tropical Medicine will give a series of eight clinical demonstrations on Tuesdays and Thursdays, at 2 p.m., from April 9th to May 2nd. There will be a course on treatment by electrotherapy at the Royal Free Hospital on four successive Wednesdays, at 5.15 p.m., beginning May 10th, and limited to sixteen. Two courses will begin on April 15th. The first is a three weeks' course at the Royal Waterloo Hospital in medicine, surgery, and gynaecology, occupying every afternoon and some mornings; the second course is in neurology at the West End Hospital for Nervous Diseases, each afternoon at 5, and lasting for four weeks, with a minimum entry of ten. Syllabuses of these courses, with information about post-graduate work in London and the provinces, copies of the general course programme, and the *Post-Graduate Medical Journal*, can be obtained on application to the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE annual general meeting of the Cremation Society of England will be held in the council chamber at 23, Nottingham Place, W.1, on Wednesday next, March 27th, at 3.30 p.m., when the council's report and balance sheet for the year 1928 will be submitted.

THE house and library of the Royal Society of Medicine will be closed from Thursday, March 28th, to Tuesday, April 2nd, both days inclusive.

SIR STCLAIR THOMSON has been elected "correspondant étranger de l'Académie de Médecine"; Professor J. H. Abt of Chicago, an honorary member of the German Society of Children's Diseases; Dr. René Gaultier, president for 1929, and Professor Hayashi, dean of the medical faculty of Tokio, an honorary member of the Société de Thérapeutique of Paris; and Dr. Henry Coppez, president of the annual medical congress known as the Journées Médicales de Bruxelles, which will be held in Brussels in 1929.

AMONG the newly elected Fellows of the Royal Society of Edinburgh are the following members of the medical profession: Dr. E. W. H. Cruickshank of the Physiology Department, Dalhousie University, Halifax, Nova Scotia; Mr. Walter Mercer, lecturer on Clinical Surgery in the University of Edinburgh; and Dr. Sydney A. Smith, Regius Professor of Forensic Medicine, University of Edinburgh.

MR. L. F. HEWITT, Ph.D., B.Sc., has been appointed biochemist at the Metropolitan Asylums Board's antitoxin establishment, Belmont Laboratories, Sutton. Dr. Hewitt is at present Gibbons Research Fellow at the London Hospital, and was formerly Freedom Research Fellow at the London Hospital, and research chemist, under the Medical Research Council, at Mount Vernon, Hampstead.

THE Gifford Edmonds prize in ophthalmology has been awarded to Mr. V. M. Métivier of the Ophthalmic Department of Edinburgh Royal Infirmary, for his essay on the causation and differential diagnosis of proptosis. This prize, founded by Miss Sophie Edmonds in memory of her brother who fell at Magersfontein, is valued at £100, and is awarded every second year.

THE Lord Mayor, accompanied by the Lady Mayoress and the Sheriffs, attended the annual meeting of St. Mark's Hospital on March 15th, illustrating the special patronage by the City of London which the hospital has enjoyed during its ninety-three years of existence. The recent increase in the number of beds at this institution has called for further extensions, including additional accommodation for nurses, a second operating theatre, and expansion of the cancer research laboratories; the cost entailed is about £30,000.

INFORMATION has just been received that the American Medical Association has joined the Association Professionnelle Internationale des Médecins (A.P.I.M.). Other recently joined members are the Medical Associations of Greece and of Palestine.

A PAPER by Messrs. J. Evans and A. O. Jones, on the determination of alcohol in urine, which was read at a meeting of the Society of Public Analysts on December 5th, and mentioned briefly in our issue of December 22nd, 1928 (p. 1140), has now been published in the March issue of *The Analyst*.

THE thirty-third post-graduate course of the Vienna Medical Faculty will be held from June 3rd to 15th, the first four days being devoted to surgery. On June 7th and 8th there will be lectures and demonstrations in orthopaedics, and on the 10th and 11th in neurology; the remaining days will be occupied by gynaecology and obstetrics. Further information may be obtained from the office of the Vienna Medical Faculty, Schlösselgasse 22, Vienna VIII.

THE forty-second congress of the Société française d'ophtalmologie will be held on May 13th, when Dr. Aubaret will read a paper on the etiology and treatment of blepharitis. Further information can be obtained from the general secretary, Dr. R. Onfray, 6, Rue de la Motte Picquet, Paris VII^{e}.

THE Droitwich Development Corporation, Ltd., has now acquired ownership of this town, including the High Street, the three principal hotels, the two existing brine baths, the park, golf links, and many miles of existing roads. The proposals for extension include the erection of a new spa at the cost of £250,000 with one of the largest covered baths in the country, and a building containing more than 100 private baths. A new theatre, concert hall, club, and cinema are also to be constructed, and it is intended that the Droitwich season shall eventually continue throughout the year.

WE have received the first issue of a journal entitled *Rivista di Radiologia e fisica medica*, which is to be published every two months at Bologna under the editorship of Professor G. C. Palmieri and an international editorial committee. Articles will be published not only in Italian, but also in English, French, and German.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

HARVEY AND HERVEY.

"W. H. C." writes: Re-reading Sir Thomas Barlow's Harveian Oration of 1916, printed in the *Journal* for October 28th of that year, I note that he refers to Abraham Cowley's poems, saying "his two poems on Harvey." Has he not confused the poem to William Hervey as one of the two he mentions, the other being the well-known Ode to William Harvey, the real subject of the Oration?

THE TRIANGULAR BANDAGE.

"INQUIRER" writes from New Zealand: I should be glad if any of your readers could enlighten me regarding the origin of the triangular bandage, so extensively used in first aid. I should like to know when and by whom it was introduced.

TREATMENT OF PREMATURE BALDNESS.

DR. M. BROWN (Glasgow) asks for suggestions for treating a nervous lad, aged 18, who is prematurely bald, and is becoming very sensitive about his appearance. There is a mild degree of sexual neurasthenia, but otherwise he is normal. Would glandular therapy help?

PROLONGED ADMINISTRATION OF CASCARA.

"SIGMOID" asks: (1) Can cascara sagrada be administered for long periods without producing deleterious effects? (2) Can the drug produce poisonous symptoms when administered for long periods, and what form will these symptoms take?

ADMINISTRATION OF ULTRA-VIOLET RAYS.

DR. ELIZABETH C. MUDIE (Glasgow), in reply to "A. M." (March 9th, p. 485), writes: (1) and (2) The best way of heating small treatment rooms is by electric radiators. A two-unit fire will keep a room 15 ft. by 15 ft. at 70° F., but in addition I advocate the use of a Sollux lamp, which can be placed over the patient to prevent chill while he is undressing. A temperature of 70° F. will not harm the lamp. (3) A steam radiator should not be used in the treatment room, as moisture in the atmosphere shuts off short ultra-violet rays. (4) It is advisable to have the lamp reconditioned at the end of twelve months, but there are instruments on the market for recording the efficiency of the burner.

ENURESIS.

DR. F. R. PROCTOR-SIMS (London, N.) writes: In reply to "K.'s" query (March 9th, p. 485), I should advise him to try suggestion. I had a case some years ago of a bright, intelligent boy about 10 years of age, who was brought to me by his father for nocturnal incontinence of urine. I spoke to the boy quietly about the drawbacks in life that the habit would be to him, and especially how it would debar him from staying at friends' houses during his holidays. I gave the father instructions about not giving the boy anything to drink close to bedtime, and to see that the boy emptied his bladder before retiring. I told the boy himself that I was giving him some medicine which would wake him up in the night if his bladder got full, and that he was immediately to jump out of bed and micturate. The mixture was a simple bitter tonic. The father called on me a week afterwards and said that there had been no trouble since, and as I have seen neither of them since, I presume it was a cure. I know of one other case which was cured by hypnotic suggestion. With regard to belladonna—if this has to be tried—I wonder if "K." has used the extract belladonna virid 1/10 grain in water t.d.s. I found it in some cases more effective than the tincture.

"L," in reply to the query of "K." on March 9th (p. 485), reports a case in a boy, aged 10, a relative-in-law of his own, who was staying with him as a guest for two months last summer holidays. Treatment consisted in orders that the boy was himself to perform all the tidying-up, washing, and drying involved by his disability, and that preliminary instruction by the women folk, and a certain amount of watching, were all that they were to do for him. The sense of shame and horror he evinced on the first morning gave an idea of the difficulty such orders would meet with in the case of a boy at home in the care of a mother habituated to do everything for him. Undeterred by reports of relapse after dramatic initial success, "L." persisted, and saw to it that no evasion of his orders was practised by anyone. At Christmas the mother gratefully wrote reporting that the resulting improvement had been well maintained. The life of an uncle of this boy had been practically wrecked by enuresis.

TREATMENT OF CHRONIC CONSTIPATION.

DR. ARTHUR E. DRUITT (Southampton) writes: Dr. Rothwell's inquiry in the *British Medical Journal* of March 9th (p. 485) prompts me to reply that I am always surprised at the frequent resort to drugs in chronic constipation without any mention of diet, in view of the uselessness of relying on drugs for an ailment which, in perhaps nine cases out of ten, is brought about by irregular habits and indiscretion in diet. When shall we learn that the wrongness of feeding on white bread can only be properly rectified by changing over to wholemeal? How is it that methods such as regular feeding, rational dietary, the adequate use of water, and the inclusion of sufficient vegetable roughage are not more practised? If, in spite of such reasonable care, the malady still persists, why, instead of falling back on drugs, should not restoration of muscular activity be sought in massage, hydrotherapy, and electrical treatment, combined with physical exercises? In emergencies cathartics hold a valuable place, but chronic constipation is not an emergency, though it is the frequent precursor of such. Unless there is reason to resort to the more specialized forms of treatment, my general practice is to recommend the use of uncooked bran, one tablespoonful for an adult or a teaspoonful for a small child; this is mixed into the breakfast porridge at the time of serving out. It lends itself well to this, and can also be mixed in milk, marmalade, etc., according to taste. It is placed, when needed, upon the table as regularly as is the sugar basin, so that people may help themselves without further comment, and carry on the treatment, if necessary, for the rest of their lives, taking it with them when on holiday. It is a treasure indeed to those who have common sense enough to use it, and who do not mind not being in the fashion of using a special doctor's prescription or the latest preparation of liquid paraffin. The construction of our w.c.'s is, in my opinion, very wrong, inasmuch as it does not encourage the natural attitude for defaecation, and herein lies, aided by natural laziness, a great contributory factor to constipation. When in Damascus, shortly after the war, I was delighted to note in the best houses a simple hole in a stone slab on the floor, through which water constantly trickled, as it was supplied by the fountain in the centre of the dwelling. The natural squatting position was then the only one to adopt, but happily for those who are thus minded and physically inclined, our own w.c.'s can, by a little ingenuity, be likewise utilized.

INCOME TAX.

Assistant—Free Accommodation.

"A. H. W." is at present remunerated by a salary, out of which he pays for his own board and lodging. It is suggested that he should take over his principal's present house, free of rent and lighting charges, and receive a smaller cash remuneration. If he does will he be assessable on the cash only, while his principal deducts the full cost to himself?

*** In our opinion, Yes; provided that the new terms of appointment make it clear that "A. H. W." will have no legal tenancy of the house and no right to sublet any portion of it.

Assistant's Expenses: Professional Subscriptions.

"J. S." is employed as an assistant to a general practitioner. The local inspector of taxes has refused to allow the deduction from the amount of the salary of the subscription to the British Medical Association, Medical Defence Union, etc., on the ground that, as the employer is responsible, those expenses are not "necessarily" incurred by the assistant.

*** The point is whether the expenses are "necessarily incurred" to earn the salary in all the circumstances. If the principal leaves it to the wish of his assistant as to whether he or she joins certain associations, etc., then the subscriptions are not "necessary," however proper and desirable. But if the principal lays it down as a condition of employment that his assistant shall belong to those associations—as he very well may—then the assistant must incur the annual expense of subscriptions, and that expense is necessarily incurred in the performance of the duties, as required by the terms of employment. We have always understood that the above statement of the position is accepted generally by inspectors of taxes.

LETTERS, NOTES, ETC.

PROPHYLAXIS OF INFLUENZA.

DR. E. R. LYTH (Isle of Man) writes: Influenza has been my *bête noire* for many years and, in spite of inoculations and sprays, I have succumbed over and over and over again. Comparatively recently I hit upon the idea of spraying or atomizing my nose and throat with an infusion of tea, and I have found this most helpful; though attending cases of influenza, it has been a new experience to escape and to keep well. There is no pain whatever in the use of the spray, and the tea mixes readily with the nasal mucus. I put in fresh tea from the breakfast teapot each morning after washing out the bottle, and this serves for the next twenty-four hours, being used, indifferently, hot or cold. Two or three compressions of the bulb for each nostril and for the throat before going out and on returning has been my custom, with an extra use of the atomizer before and after seeing any suspicious case.

ENDOGENOUS OR EXOGENOUS.

DR. F. P. DE CAUX (London, W.) writes: Sir James Barr, writing in your issue of March 9th (p. 475), stated that, after douching his nose with saline, a few drops of clear fluid would drop out on lowering his head. It may interest him to know that I douche my nose regularly with glycerinum thymol compositum (*B.P.C.*), and that on lowering my head several drops of pink-coloured fluid run out, and that, if I do not lower my head until several hours have elapsed, when I do so the pink fluid still runs out. If Sir James were to colour his saline with a solution of carmine he might think of another reason than the one he gives.

UNUSUAL SYMPTOMS OF PROSTATE ENLARGEMENT.

"J. C." writes: I was interested to see in the *Journal* of February 9th (p. 233) that when one of Mr. Grey Turner's patients put his hands into water he experienced an instant urge to micturate. I have spoken to surgeons about the reflex connexion between the bladder and hands, but have never obtained any satisfaction. In my own experience when the bladder is over-distended there is acute pain in both palms on starting urination. I wonder if Mr. Grey Turner has noted mental changes in the direction of *tête montée* in early cases of prostate enlargement?

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 71.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

287. Polyarthritis and Acute Myelogenous Leukaemia.

G. RIZZO (*Il Policlinico*, Sez. Prat., February 18th, 1929, p. 223) describes a case of acute polyarthritis followed by acute myeloid leukaemia. Two months before admission to hospital the patient had a sore throat with difficulty in swallowing and breathing, which lasted four days, and was followed by pain and swelling of the right ankle and both knees; later both wrists became swollen, with limitation of movements and severe rheumatic pains not yielding to salicylates or iodine. The Wassermann reaction and blood cultures were negative, and the gonococcus was not detected. The blood was slightly anaemic, and there was a leucocytosis of 20,000 per cubic millimetre, of which 86 per cent. were polymorphonuclear leucocytes. The rheumatic pains became more severe and associated with fever and profuse sweating. Later, ulcerations appeared on the tongue and gums, spreading to the tonsils and affecting almost the entire mucous membrane of the mouth; there was purulent discharge from both ears. General asthenia with increased anaemia now supervened, and at less than three weeks before death the white cells of the blood first showed the characteristic qualitative changes seen in myelogenous leukaemia; the lymphocytes were reduced to 0.5 per cent. and the polymorphonuclears to 19.5 per cent., whereas there were 18 per cent. myelocytes, 11 per cent. promyelocytes, 39 per cent. myeloblasts, and numerous nucleated and immature red cells. The spleen and liver were enlarged. The heart was not enlarged or displaced; there was a soft apical systolic murmur, which became more manifest and prolonged towards the base. During the last week of the illness a general haemorrhagic state developed. On the day before death the leucocytosis was 44,000 and the red cell count was 1,200,000 per cubic millimetre. The points of interest in the case noted are the initial angina, followed by polyarthritis, and the prolonged proleukaemic period.

288. Scarlatinal Nephritis.

B. S. HIRSCHBERG and M. E. SSUCHAREWA (*Jahr. f. Kinderheilk.*, January, 1929, p. 340) state that 167 (19.75 per cent.) of the 845 cases of scarlet fever admitted to the infectious department of the children's clinic of the Second State University at Moscow were complicated by nephritis. The incidence of nephritis increased with the age of the patient, being 4.3 per cent. below 1 year, 13.3 per cent. between 1 and 3 years, 18.8 per cent. between 3 and 5 years, 22.1 per cent. between 5 and 8 years, and 23.2 per cent. between 8 and 12 years. The cold season exercised a certain influence on the frequency of nephritis, 19.6 per cent. being found in the spring, 15.6 per cent. in the summer, 20 per cent. in the autumn, and 21.9 per cent. in the winter. The complication may occur at any stage of the infection, but the maximum incidence (23.3 per cent.) was in the third week, while a fair proportion of cases were found in the second week (19.7 per cent.) and fourth week (17.9 per cent.); 11.9 per cent. of the cases commenced in the first week of scarlet fever. Nephritis was somewhat more frequent after severe than after mild attacks of scarlet fever. Throughout the course of the nephritis a considerable involvement of the cardio-vascular system was observed, and was chiefly manifested by rise of blood pressure, dilatation of the heart, and accentuation of the second sound. Increase in weight was found to be a premonitory symptom of nephritis. In a fair number of cases the nephritis was present only in slight degree; in such instances it was only by repeated examination of the urine that a few red cells and traces of albumin could be found in some parts of the urine. Rise of blood pressure and accentuation of the second sound were then of considerable diagnostic value.

289 Pleural and Pulmonary Lesions in Rheumatic Fever.

J. R. PAUL (*Medicine*, December, 1928, p. 383) calls attention to the frequency with which pleurisy occurs as a complication in rheumatic fever. Citing illustrations from the literature of this fever extending over a century, he shows that the conception of the disease as one of all the serous membranes, with a preference for the joint cavities and pericardium, is by no means new. He discusses the question whether a specific lesion of the lung substance proper can be recognized as due to the rheumatic infection, and suggests that the recognition of structures similar to the Aschoff bodies found in the myocardium gives some support to the hypothesis. The difficulty is emphasized of distinguishing between pulmonary and pleural lesions caused by terminal and complicating infections and those which may be due directly to rheumatism, particular reference being made to Coombs's description of the signs of pulmonary collapse at the left base in rheumatic carditis, which is sometimes mistaken for pneumonia. Paul believes that pleurisy, generally with effusion and a copious fibrinous exudate, is a relatively common complication of rheumatic fever, and is usually associated with the more severe cases of carditis and pericarditis, adding considerably to the gravity of the prognosis.

290. Incipient Tuberculosis.

J. HEIMBECK (*Norsk Mag. f. Laegevid.*, January, 1929, p. 18) records his observations on the incidence of tuberculosis in nurses at the Oslo communal hospital since 1924. He found that among 282 nurses aged from 20 to 25 with an old latent tuberculous infection the disease very seldom became activated and gave rise to symptoms. On joining the hospital 299 nurses were found to be absolutely free from tuberculous infection both by clinical examination and the Pirquet test; 57 of them were examined by *x* rays without showing any signs of disease. It was found that all the fresh cases of tuberculous infection occurred in this group of nurses as soon as they were exposed to infection. Clinical, serological, and *x*-ray examination showed that the tuberculous infiltration of the lungs was the immediate result of an exogenous infection. In several cases pleurisy and erythema nodosum proved to be manifestations of this tuberculous infection.

291. Goat Serum Toxin-antitoxin.

L. BIVINGS (*Arch. of Pediat.*, December, 1928, p. 736) records his observations on 350 cases recently immunized in the health clinic of the city of Atlanta with goat serum toxin-antitoxin, and in part subsequently tested by Schick's method. The results were very gratifying. Whereas in the past three years the horse serum product had given rise to severe reactions in at least 40 per cent., only 2 per cent. of the goat serum series showed any reaction. The immunizing value of goat serum toxin-antitoxin compared favourably with the horse serum product. Bivings comes to the conclusion that, in view of the specific sensitization to animal serums following large doses of serum and possibly the use of toxin-antitoxin, goat serum toxin-antitoxin should be employed to prevent the dangers of sensitization to horse serum products of which most of the prophylactic and therapeutic serums are made. He is of opinion that sheep serum probably has the same advantage.

Surgery.

292. Salivary Lithiasis.

L. ARAGÓ (*La med. Ibera*, January 26th, 1929, p. 124) defines four types of calculi found in the buccal cavity: (1) those which develop in the salivary glands and their ducts; (2) those which originate in the mucous glands of the walls of the cheek and lips (very rare); (3) those which are formed between the teeth and the gums (the most frequent variety); and (4) those which are deposited on prosthetic apparatus. The chemical constitution is the same in all, since they are formed principally of earthy phosphates and carbonates. Obstruction to the flow of saliva and persistence of food in the mouth are conditions which favour their formation, so that they are usually found in neglected mouths. The submaxillary glands and ducts are most frequently affected, probably owing to the stagnation of the saliva and the larger size of Wharton's duct. Foreign bodies, such as small splinters of wood, fish bones, and fruit seeds, are more likely to find their way into the opening of Wharton's duct than elsewhere. In Closmadeuc's statistics Stenson's duct was affected in 11 and Wharton's in 101; the combined statistics of Czygan, Buchwald, and Wenzel show that 61.4 per cent. of the calculi were found in Wharton's duct and the submaxillary gland, 20.4 per cent. in the parotid and Stenson's duct, and 18.2 per cent. in the sublingual gland and its duct. The number of calculi varies from one to seven in Wharton's duct and up to twenty in the submaxillary gland; they are more often found in males than in females, and may occur at all ages, but are most frequent in adults. The symptoms are similar, whatever the gland and duct affected. The first sign

is almost always an intermittent swelling of the affected gland at meal times or at the sight of food. The swelling is at first uniform and disappears on pressure; in other cases it is accompanied by pain or salivary colic when the obstruction is complete. The foreign body may be felt on bimanual palpation, or the hard surface may be detected with a sound or by puncture. The diagnosis is readily established by *x* rays. The prognosis is favourable in localized salivary lithiasis, but is aggravated by septicaemia, meningitis, or oedema of the glottis. Treatment consists in extraction of the calculus through an incision in the duct or gland. Partial or complete extirpation of the gland may be indicated in cases of recurrent lithiasis when the glandular parenchyma is intensely degenerated.

293. Appendix Conditions in Young Children.

E. W. PETERSON (*Annals of Surgery*, January, 1929, p. 48) contends that appendicitis can occur as early as the first week of life, and that its rarity in infants has been too greatly emphasized. The diagnosis of appendicitis in very young children is so difficult that the condition is frequently overlooked or not thought of under the age of 2. Many cases of indigestion-colic, gastritis, gastro-enteritis, acidosis, and cyclic vomiting are, he thinks, really unrecognized appendicular disease. The mortality in acute appendicitis in early life is very high, in nurslings over 70 per cent., and in 80 cases of children under the age of 2 it was 50 per cent.; under 6 years the mortality is estimated as from 15 to 40 per cent. Purgation and procrastination are held responsible for the majority of deaths. Out of 100 patients operated on by Peterson 8 were under 12 months old, and this condition was associated with acute intussusception; in the age period 1 to 2 years there were 5 cases; from 2 to 3 years, 10 cases; from 3 to 4 years, 9 cases; from 4 to 5 years, 18 cases; from 5 to 6 years, 23 cases; and in the 6th year, 27 cases. Males were affected in 71 and females in 29 instances. There was a mortality of only 6 per cent. Peterson believes that appendicitis is one of the common causes of intussusception, and that appendicitis should always be suspected when a hernia gives subjective symptoms of any kind, it being the exception to find a normal appendix in a child who has had a hernia, unsupported by a truss, for any considerable period of time. Early recognition and prompt surgical treatment of appendicitis give good results even in infants and the younger group of children.

294. Ganglion of the Hip-joint simulating Femoral Hernia.

C. HAMMESFAHR (*Zentralbl. f. Chir.*, February 2nd, 1929, p. 285) describes the case of an elderly man who fell while wheeling a barrow. Immediately after this severe strain of his thigh the muscles became swollen, and a painful swelling, as large as a hen's egg, appeared beneath Poupart's ligament. The pain increased and peculiar tingling sensations extended as far as the knee and radiated to the back. The patient thought that he had a hernia and requested an operation. When admitted there was a hard, irreducible, slightly mobile oval swelling below Poupart's ligament. Very forcible pulsation over the swelling made the diagnosis of hernia uncertain, and preparations were made to ligature the vessels. At the operation a smooth swelling of the size and form of a hen's egg was found beneath the femoral vessels, and was dissected out with great difficulty. A pedicle of the thickness of a lead pencil communicated with the joint; a probe was passed easily through its lumen into the acetabulum. The cyst wall was dissected out and the pedicle was ligatured. The wall varied in thickness from 1/18 to 1/12 inch, and consisted of scar-like connective tissue. Uninterrupted healing followed, with daily passive movements of the joint. Hammesfahr believes that small ganglia of the hip-joint may account for some obscure cases of coxalgia which have been described as functional or attributed to malingering.

295. Phlebitis following Simple Fractures.

JEANNENEY (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, February 10th, 1929, p. 116) reports two cases of extensive thrombo-phlebitis—a rare complication of non-compound fractures. He states that it appears to be attributable frequently to (1) the site of the fracture; (2) the presence of venous thrombosis, due to the injury; or to (3) a latent systemic bacterial infection which may complicate any fracture. He adds that in cases of thrombo-phlebitis it is especially necessary to order absolute rest, with elevation of the limb, particularly in cases presenting symptoms of previous venous lesions, such as varices or old phlebitis. Calcium salts should not be prescribed, or, if required, very small doses alone are advisable. Passive movements of the injured limb should be performed with great caution.

Therapeutics.

296. Iodine Treatment of Graves's Disease.

M. LABBÉ (*Ann. de Méd.*, January, 1929, p. 5) advocates the administration of iodine in cases of Graves's disease in daily doses of 1½ grains (in form of pills), or even as much as twice that dose. This is usually well taken without producing toxic effects, such as congestion and irritation of the eyes or skin eruptions. In true cases of this disease the benefit is rapid and general; at the end of a week the tachycardia, excitement, trembling, and digestive disturbances are diminished, wasting is arrested, and the patient puts on weight, the basal metabolism being lowered. If the treatment is stopped the symptoms return. The results and the rapidity of the reaction vary with different patients, and in some cases no improvement occurs in spite of prolonged treatment. The author has seen no patient cured by the iodine treatment, but many can be kept in good health by continuing it. The action of iodine affects the symptoms in various degrees; the goitre itself is not changed in volume, though it may become less vascular and cease to pulsate; the exophthalmos is not affected; the tachycardia is often but little influenced; the metabolism, however, returns to normal and the patient puts on weight, trembling is diminished, and the general state is much improved. Iodine is useful in preparing the patient for thyroidectomy, so that the mortality from the operation has been reduced to about 2 per cent.; it is superior to preparation by ligature of the thyroid arteries, or by radiotherapy. Iodine also assists the slower radiotherapy which may be prolonged to a complete cure. The operative treatment, which is preferred in America, is still considered dangerous and uncertain in France.

297. Quinidine Sulphate in Cardiac Arrhythmia.

C. LIAN (*Bruxelles-Médical*, February 10th, 1929, p. 429) remarks that quinidine sulphate is capable of diminishing extrasystolic arrhythmia, and uses it in cases in which the arrhythmia is a translation o a myocardiac or nervous hyperexcitability. He has obtained encouraging success without resorting to large doses. The technique is as follows. For two days he gives one 0.20 cg. dose daily of quinidine sulphate; for the next two days two doses a day; and for the following ten days three doses a day, one before each meal. This course is followed by five days' cessation of treatment. The patient is then given a further course of ten days' treatment; a seven days' course follows; and then a five days' course, with gradually increasing intervals between each course. In cases where there is a slight cardiac insufficiency 1/10 mg. of crystallized digitaline a day in addition to the quinidine sulphate is given. In cases where there is much cardiac insufficiency, or bradycardia, quinidine sulphate is not used. Lian states that, although it was rare for extrasystole to disappear completely under the sole influence of quinidine sulphate, the results were good. The patients became less conscious of the painful sensations produced by extrasystole, as these became less strong and less frequent. The author attributes the improvement to the prolonged course of cure with increasingly long intervals between each period of dosage.

298. Stimulation of the Growth of Hair.

ELSA EICHOLZ (*Dermat. Woch.*, February 2nd, 1929, p. 161) has investigated the action of various agents in stimulating the growth of hair in rabbits, mice, and guinea-pigs, patches of skin being previously shaved and epilated by calcium sulphide and zinc oxide. It was found that chrysarobin and sunlight rays caused hyperaemia and gave the best and quickest growth of hair. Gentle rubbing of the skin with vaseline, benzine, and benzol, and even gentle finger massage, caused slight revival of hair growth, but if the rubbing was severe, so as to produce hyperaemia, the results were almost equal to those obtained with chr[illegible]. Cholesterin-vaseline and trilysin (an [illegible] cholesterin) gave the same results as simple vaseline; trilysin did not appear to possess any specific property as a hair restorer.

239. Malarial Treatment of Syphilis.

H. RUGE (*Urol. and Cutan. Rev.*, January, 1929, p. 8) recalls that the first application of malarial treatment to cases of early syphilis to prevent the occurrence of later complications was due to Kyrle, who based his conclusions on observations of 600 cases. Its value in the early stages of secondary syphilis has not been proved, but it may be of value in the later stages. The best time for malarial treatment is said to be during the fourth to the sixth year after infection. Treatment by malaria in the early stages of syphilis has no advantage over energetic ordinary treatment, but in the

subsequent latent stage a thorough course of malarial treatment may prevent the onset of tabes and general paralysis. In all cases the malarial treatment should be preceded by a course of salvarsan of 4 to 6 grams, and followed by a course of 3 to 5 grams of neosalvarsan. Bismuth may be used with the salvarsan from the first, as well as in the intervals between the paroxysms. The malarial treatment should also be followed by two courses of specific after-treatment.

Neurology and Psychology.

300. Agglutinin Formation in Mental Cases.

SINCE the appearance of agglutinins in the blood following vaccination or infection occurs regularly in so many individuals and animals, F. A. PICKWORTH (*Journ. Mental Sci.*, October, 1928, p. 709) concludes that this phenomenon is doubtless connected with successful resistance to the deleterious effects of the organisms, and that the non-production or abnormalities in the production of agglutinins following injection of bacteria represents a pathological process, probably of the nature of sepsis. Seven graphs are supplied to illustrate the varying reactions of a series of mental hospital patients to injections of T.A.B. vaccine. *Agglutinins may* disappear from the blood in febrile conditions, and Besredka's experiments have shown that high agglutinins may be reduced by the cessation of the production of that particular agglutinin, coincident with the alteration or destruction of the existing serum globulin. Pickworth remarks that the upper part of the small intestine is sterile, and the colon type of bacilli should not occur above the lower part of the jejunum. Arnold and Brody have noted that when the reaction of the duodenum is for long neutral or alkaline the bacterial flora changes to that found in the ileum or caecum; abnormal organisms undoubtedly occur in the upper duodenum in such conditions as pernicious anaemia. It has been shown that leucocytes take up bacteria and transport them to the liver and spleen, where, according to Adami, the bacteria multiply until the tissues react, causing their lysis; the liberated toxins then destroy the neighbouring tissue. Tissue invasion and bacteriaemia urgently demand agglutinin formation through the presence of new deleterious bacterial protein. There is an important connexion between focal and intestinal sepsis, and an undoubted relation between the leucocytes and agglutinin formation. Two important causes of focal sepsis are a bacteriaemia and a depletion of leucocytes. Pickworth has noted changes in the small intestine, such as dilatation and ballooning, and, doubtless, chronic bacterial invasion is common in the acute phases of mental disorder. The frequent occurrence of delusions of poisoning further supports the theory of gastro-intestinal sepsis. Damage to the intestinal epithelium permits the absorption of deleterious bacterial products, and, if these products are toxic to nervous structures, this will give rise to intellectual and emotional deterioration or to specific nervous effects. Local damage of tissue in a patient with bacteriaemia may result in a bacterial focus with possible deleterious local effects. The interrelation between focal sepsis and the variation in agglutinin formation in the insane may occur through high intestinal sepsis caused by infection with paratyphoid or food-poisoning organisms. Poisoning and loss of leucocytes in the intestinal tract, a bacteriaemia of intestinal organisms, and reinfection from pyaemic focal sepsis are highly probable factors in this relation.

301. Centro-lobar Cerebral Sclerosis.

J. MARIE (*Ann. de Méd.*, December, 1928, p. 545) remarks that in recent years a new type of cerebral sclerosis has been isolated; it is characterized by marked anatomical lesions and clinical symptoms. Two varieties of this disease have been observed—a chronic form, first reported by Marie and Foix in 1913; and a subacute and fatal type, described by Schilder in 1912. From these last two observers the name "malady of Schilder-Foix" has been given to the disease. In Schilder's case, a girl aged 14, the affection commenced insidiously with apathy, vomiting, and loss of sight. Blindness became total in four months, the base of the eye showing papillary oedema. A right hemiplegia with dysarthria developed, and death with marasmus ensued in six and a half months. The necropsy revealed a symmetrical, yellowish, massive centro-lobar lesion of varying consistency, which invaded the whole of the white substance of the occipital, parietal, and posterior part of the temporal lobes. This mass was separated from the cortex by a fine band of healthy fibres. In the patient of Marie and Foix, a lad aged 18, the disease commenced as an extremely spastic triplegia, which in five days progressed into a quadriplegic syndrome with aphasia. The spastic triplegia persisted for ten years, the patient dying from pulmonary tuberculosis. A bilateral, symmetric, greyish hard area of sclerosis was found, which involved the white substance of the hemispheres and extended from the occipital lobe to the Rolandic convolutions, the cortex and a fine border of subcortical myelinic fibres being uninvolved. These cases were similar in the following points: the massive attack of the cerebral white substance and of the convolutions; the absolute integrity of the cortex and a fine border of subcortical myelinic fibres; and the symmetry or tendency to symmetrical lesions. Marie gives a detailed description of the anatomical pathology, and classifies the disease in four groups: in the first, the subacute, there is softening of the nervous tissue, as in suppurative encephalitis; in the second and third the consistency of this tissue is increased; and in the fourth it is very dense, and marked atrophy of the white substance is present. The author remarks that these groups really represent stages in the development of the disease, and depend on its duration.

302. Congenital Auditory Imperception.

C. WORSTER-DROUGHT and I. M. ALLEN (*Journ. Neurol. and Psychopath.*, January, 1929, p. 193) believe that cases of congenital "word-deafness" are of considerable rarity, and that in the past many of these have been misinterpreted. They describe fully a case which they regard as one of congenital auditory imperception, the term "word-deafness" being considered too limited. Complete word-deafness, or, more strictly, word-meaning-deafness, is the most important element, but some auditory agnosia is present. Word-blindness in small degree, slight agraphia or dysgraphia, and a pronounced speech defect are associated secondary elements. The disorganization of the speech mechanism has led to the development of a method of expression which is of the nature of so-called "idioglossia." The case reported illustrates the interdependence of each and every elemental part of the speech mechanism, and especially the dependence of normal speech development upon the appreciation of variations in sounds. The observations confirm the modern view that the speech mechanism cannot be divided into clearly defined "centres," but must be regarded as a physiological mechanism which functions as a complete whole. The disorder is probably caused by a biological variation or a local aplasia, but birth injury cannot be definitely excluded. The case raises important questions, including the effect of congenital word-deafness upon the development of speech defects such as idioglossia, the influence of such a defect upon the development of general intelligence, the psychological reactions in those affected with this disability, their influence on behaviour and delinquency, and the importance of applying special methods of education to these patients in order to enable the individual to attain a self-supporting position and to prevent the development of antisocial tendencies.

Obstetrics and Gynaecology.

303. Premature Rupture of the Membranes.

MARGARET SCHULZE (*Amer. Journ. Obstet. and Gynecol.*, January, 1929, p. 20) states that in a series of 6,500 deliveries the percentage of dry labours was 9.3. Factors predisposing to early rupture of the membranes were primiparity, overdistension of the uterus from hydramnios, plural pregnancy, large size of the child, and contracted pelves with non-engagement of the head. In some cases, however, the immediate cause appeared to be due to variations in tensile strength of the membranes from a deficient development of the connective tissue. Labour ensued within one hour of the membranes rupturing in more than half these cases, and only in about 10 per cent. of them was there a delay of more than twenty-four hours. Induction of labour by castor oil and quinine, subsequent to rupture, was successful in 90 per cent. of cases. The first stage of labour (dry) was shortened, occupying six hours or less in 37 per cent. of primigravid and in 64 per cent. of multigravid patients. The second stage was not influenced. Only in 8.4 per cent. of cases did labour last more than twenty-four hours. Operative intervention was more necessary in the dry labours, but in two-thirds of the cases where manipulation was required some other cause of dystocia was discovered. Despite this the maternal mortality in this series was *nil*, while the foetal mortality was under 5 per cent. In 31 per cent. of cases inflammatory reactions of the cord were present, and were the cause of foetal death. This ascending omphalitis occurred where labour had been prolonged, or where some form of dystocia had called for remedy by manipulative intervention. In the series of 6,500 cases a febrile puerperium was present in 13.5 per cent., whereas in the dry labours the percentage mounted to 17. The maternal morbidity is therefore higher when the membranes rupture early in labour. Where the

labour was dry, but uncomplicated in other respects, the issue was usually satisfactory; but where early rupture of the membranes occurred with dystocia from some independent cause labour became a more complex affair. Treatment by Voorhees's bag did not prove successful in lessening foetal mortality or maternal morbidity.

304. Foetal Injuries in Breech Delivery.

ACCORDING to E. B. PIPER and C. BACHMAN (*Journ. Amer. Med. Assoc.*, January 19th, 1929, p. 217) infant deaths in uncomplicated breech labours are due to three accidents: compression of the cord, the occurrence of nuchal positions of the arm, and delay in delivery of the after-coming head. The first accident must be accepted as inherent in the mechanism of breech labour, but the two latter are more often due to poor judgement and technique. As a means of preventing the death of the foetus in these presentations the authors advise elimination of the second and, if necessary, of the late first stage of labour by bringing both feet down early and immediate extraction. For the performance of this operation two procedures are essential: complete anaesthesia, and thorough dilatation, amounting almost to paresis, of the lower uterine segment, cervix, and soft parts of the lower birth canal. The technique of extraction must be such that nuchal positions of the arms are avoided and the after-coming head is guided into the pelvis with the face directed posteriorly. In the authors' method, each step of which is described and instructively illustrated, after the feet have been brought down, the foetal back is rotated posteriorly by drawing on the posterior foot so that the child "sits in the hollow of the maternal sacrum." The foetus is then completely rotated, thus bringing the buttocks out under the symphysis. Traction is then applied until the points of the scapulae appear at the vulva. The arms are now "levered out" by Potter's method, and delivery of the first shoulder draws the head into the pelvis and engages it in the diameter opposite in name to that of the delivered shoulder. The head may then be delivered by standard manual methods, but should any difficulty arise (the authors make only one gentle manual effort) forceps should be promptly used. The authors believe that this procedure will save many infants hitherto lost by long-continued manual manipulations.

305. Bacteriaemia after Labour.

ACCORDING to E. KULKA (*Zentralbl. f. Gynäk.*, January 26th, 1929, p. 202) bacteriological examination of blood taken from the arm at the correct time demonstrates in many cases that a bacterial invasion of the blood occurs during and shortly after labour; this invasion may occur in cases in which childbirth and the puerperium are apyrexial. The presence of pathogenic organisms in the blood-stream in cases of non-febrile abortion has been proved by Schottmüller. In a group of forty cases of spontaneous and other deliveries, with or without puerperal pyrexia, Kulka found that seven patients showed the presence of bacteria in 20 c.cm. of blood removed from the arm ten minutes after delivery of the placenta; these included four in whom no fever occurred during or after labour. In five of the seven cases blood cultures showed the presence of *B. coli*; the children were delivered spontaneously, but in two instances the membranes had ruptured prematurely. The organisms in the other two cases, one of which was afebrile, were a non-haemolytic streptococcus and *Staphylococcus albus* respectively. Kulka believes that many of the negative blood cultures associated with puerperal infection are due to the blood not being abstracted until the supervention of high fever or rigors; at such a stage the invading micro-organisms may have been dealt with by the bactericidal activities of the body.

Pathology.

306. The Infectivity of Erysipelas.

WAGNER-JAUREGG based his malaria treatment of general paralysis on the observation that intercurrent acute infective diseases sometimes had a beneficial effect; occasionally, however, the cerebro-spinal fluid does not return to normal after a single course of malaria, and reinoculation may either produce only a weak response or none at all. THERESE KINDLER (*Derm. Woch.*, January 5th, 1929, p. 7) therefore attempted to excite an analogous febrile reaction by direct inoculation with erysipelas, incidentally testing the reputed infectivity of this condition. The failure of other workers in previous attempts at inducing erysipelas with culture inoculations had been ascribed to a loss of virulence of the cultured strains. Kindler chose three cases of clinical neurosyphilis with positive cerebro-spinal fluid; they had proved resistant to malaria therapy and other forms of treatment. The patients had no signs of other organic disease or history of previous erysipelas. Fourteen inoculations in all were given, consisting (1) of subcutaneous injections of the fluid from vesicles of recent bullous erysipelas; (2) serum obtained from the periphery of an erysipelas lesion applied to scarified areas on the forearm and between the fingers; and (3) gauze which had been used as dressings in a case of acute erysipelas applied to scarified areas. These three methods were also applied to skin in which dermatitis had first been induced by the local use of croton oil and blistering with cantharides plaster. All these attempts produced negative results. Kindler mentions that Kihn has shown that general paralytics are very sensitive to furunculosis and pyogenic lesions of the skin. She also found no difficulty in inoculating an impetigo pustule in one of these erysipelas-resistant cases. She concludes, though the material is small, that possibly the infectivity of erysipelas has hitherto been overestimated.

307. Tissue Changes after Malarial Treatment of General Paralysis.

R. B. WILSON (*Brain*, December, 1928, p. 440) states that the outstanding feature in sixteen cases of general paralysis in which necropsies followed within six weeks after malarial treatment was a strong glial proliferation and the richness of iron in the walls of the blood vessels and microglia. The increase of iron probably indicated an increased permeability of the blood vessels. The presence of numerous macrophages in the meninges was regarded as the expression of an increased phagocytic power, evidence of which had been found in studies of the cerebro-spinal fluid by others. Spirochaetes were found in one case. No evidence was found of a change to a more specific type of reaction. In the earliest stages only there was a considerable predominance of lymphocytes in the meninges, whereas in the cortical perivascular spaces plasma cells predominated throughout. Towards the end of the period the infiltration tended to increase in the arterioles and venules and to decrease in the capillaries. This period of exacerbation was followed by one of restitution, as shown by a gradual improvement in the arrangement of the cortical layers and nerve cells and a considerable reduction of infiltration and glial proliferation, which were found in thirteen cases, one of which came to necropsy after six weeks, and others up to two and a half years after malarial treatment. Among the cases coming to necropsy from six months to two and a half years after treatment, six showed scattered foci of intense inflammation in which the mesodermal tissue had strongly proliferated. Spirochaetes were found in five cases. No improvement in the serological reactions of these cases followed treatment, whereas in cases with histological improvement there was also corresponding serological alteration.

308. A Simple Test for Albumin in Urine.

C. BOSE (*Indian Med. Gazette*, January, 1929, p. 17) describes a simple, delicate, and reliable means of detecting albumin in the urine which is said to possess advantages over the nitric acid test in that it does not precipitate mucin, urea, or urates, unless the last are greatly in excess. The test is applied in a similar way to that of Heller with nitric acid, by allowing a filtered saturated solution of saccharin in water to run slowly down the side of a test tube by means of a pipette and to settle at the bottom. If even a trace of albumin is present a sharply defined white ring forms slowly at the junction of the two fluids. The same result is obtained as with strong nitric or picric acid, but the saccharin solution, being perfectly harmless, colourless, and odourless, and having no toxic or caustic action, possesses the additional advantage of being easily carried in the pocket in a stoppered bottle for use in the patient's home. Since the solution does not precipitate mucin it has an advantage over the heat and acetic acid test. It is added that the albumin-precipitating property of saccharin was discovered while it was being used as a sweetening agent with milk.

309. The Cerebro-spinal Fluid and Hypophysis.

A. GEESINK and S. KOSTER (*Nederl. Tijdschr. v. Geneesk.*, December 8th, 1928, p. 6046) examined the cerebro-spinal fluid obtained by suboccipital puncture of six normal dogs, and of three other dogs, in one of which the hypophysis had been completely, and in two almost entirely, removed. In the normal dogs the action of the fluid, as shown by the production of contractions in the uterus of a guinea-pig, corresponded to that of a 1 in 400 solution of pituitrin. In the case of the dogs in which the hypophysis had been more or less completely removed, distinct uterine contractions were obtained with fluid removed from eight to fourteen months after the operation, though in a less marked degree than in the normal dogs. The cerebro-spinal fluid of the dogs in which the hypophysis has been completely removed produced a slighter contraction than that of the animal in which the hypophysectomy had not been quite complete.

ELIMINATION of URIC ACID

in Rheumatism, Lumbago, Sciatica, Neuritis, etc., by

AGOTAN

(HOWARDS)

Some Clinical Reports:—

M.R.C.S., L.R.C.P., writes:
"One can only theorise about the way in which Agotan and similar substances bring about the elimination of uric acid. That Agotan does so can be proved to demonstration and sufficiently accurately for clinical purposes by the phosphotungstic estimation of uric acid in the urine. This is accompanied by rapid mitigation of symptoms."

Capt. (R.A.M.C.):
"In our wet and cold camp of 1926, men were continually reporting sick with sciatica or lumbago. Conditions rendered most of the accessory means of treatment most difficult, but Agotan—10 grs. thrice daily—cleared the trouble up in 3 or 4 days' time despite the adverse conditions. In several cases taken at their very inception, so to speak, three doses proved sufficient."

M.B., B.Sc., D.P.H.:
Reports that he has achieved success with Agotan when salicylates, iodides, ionisation and diathermy, etc., have all been, to use his own expression, "utterly futile." "With Agotan," he writes, "one can safely prophesy an ultimate cure. Even in cases where ultimate resort had had to be made to morphine this can be discontinued in a very short time. Progress towards recovery is never interrupted by exacerbations as is so common with the majority of other drugs."

M.D. (London):
"I prefer to regard sciatica as a neuritis and not merely a neuralgia, and I further believe that the commonest cause of neuritis is uric acid. At all events my most rapid and lasting results in its treatment have been obtained by that excellent preparation Agotan. I have had marked success with it, too, in that very troublesome condition gouty urticaria, both as a curative agent, and, I think, also as a preventive."

M.B., Ch.B.:
"The gouty subject has a notoriously sensitive stomach and an impatient disposition. Many remedies for his condition which we know to be good have to be abandoned for one or other of these two reasons. Agotan, which is a recognised eliminant of uric acid, can be used in such cases in the form of an ointment, either alone or assisted by radiant heat. This ointment should be rubbed in not merely over the area actually affected in cases of 'rheumatism' or 'gout' but for several inches all round, so as to ensure absorption of a sufficiency of the drug. Both acute and chronic conditions of this kind are markedly benefited by it, and in neuritis it is a veritable boon to all concerned."

M.D., C.M., D.P.H., etc.:
"I have run through the whole gamut of B.P. remedies, and I have tried, I think, all the proprietary uric acid solvents of the present day, but after many years of experience I have come to rely on Agotan as the most trustworthy preparation at present available. The conditions in which it may be prescribed with confidence embrace all forms of subacute rheumatism, muscular rheumatism or myalgia, including sciatica, brachial neuritis, and gout, whether acute or chronic, and most of the gouty skin diseases. The last group often yields remarkably well to Agotan.

N.B.—Agotan is not a patent medicine. It is official in the B.P.C. 1923

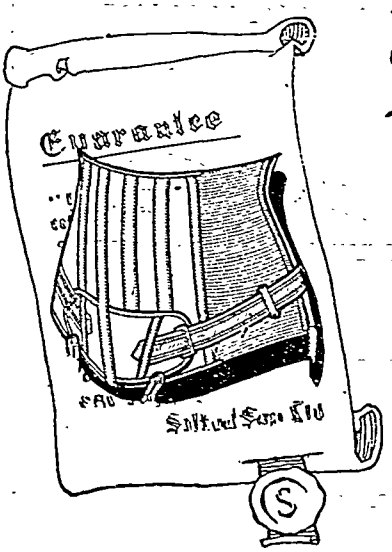
SURGICAL SERVICE
SALTAIR

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.



The Guarantee behind each Appliance made by Salts

Do you—as a Medical Man—realize the ***thoroughness*** of such a guarantee?

It means that the appliance specially made by us for your patient will be altered, exchanged, or accepted back if unsuitable (*vide* our guarantee).

That's a safeguard to you and your patient such as no firm of less reputation in medical circles dare provide.

The design of every one of our appliances is based on the latest surgical practice, and a notable case in point is

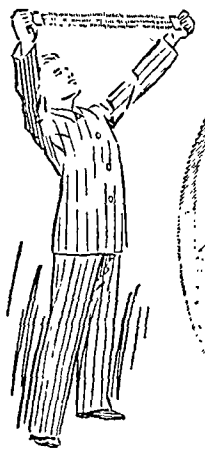
SALT'S VISCEROPTOSIS BELT,

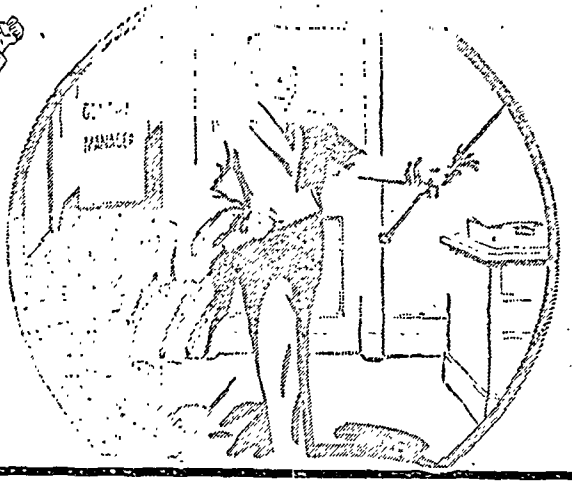
a belt-corset that possesses unique advantages—

1. Not only ***lower*** but ***upper*** support, thus maintaining the entire viscera.
2. A special pad lying right across lower abdomen.
3. Carried well above the waist.
4. Made in various grades and qualities to meet the needs of all.

SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

COPYRIGHT ESTABLISHED 1793.





There's a reason why the busy man wears

"Tricoline"

SHIRTS, COLLARS & PYJAMAS

A "WEMCO" Fabric.

IT is because, in addition to their comfort and economy, they represent the finest value and variety that can possibly be offered. Thoroughly well made in a wide choice of plain shades and tasteful stripes, all the colours are guaranteed fast to laundering.

"TRICOLINE" SHIRTS, COLLARS and PYJAMAS are sold by leading Hosiers, Outfitters, and Stores everywhere. If any difficulty, write M15, "TRICOLINE" House, 19, Watling Street, London, E.C.4.

Prescribed in numerous cases *of nervous and heart disorders, also rheumatic conditions, etc.*

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

WRIGHT'S LYSOL

A handy graduated measure is provided with every bottle.

The quality of WRIGHT'S LYSOL has never been questioned

It is safe to prescribe Wright's Lysol—safe because you know that your patients will then get a pure and highly refined Lysol controlled by the Rideal-Walker test. Wright's contains no free alkali—does not stain or irritate—gives certain results. It is widely used by the profession;

Hospitals and Nursing Homes prefer it.

Tell your patients always to say "Wright's" before "Lysol."

British owned and British made by the makers of the well famed Wright's Coal Tar Soap.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 Northampton), who can be seen in London by appointment.

HAYDOCK LODGE, NEWTON-LE-WILLOWS, LANCASHIRE.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

Stoke and Wolstanton Union.

DEPUTY RESIDENT MEDICAL OFFICER.

Applications are invited from fully qualified medical gentlemen for the appointment of Deputy Resident Medical Officer at the London Road Institution of this Union. The Institution has accommodation for 1,154 inmates, the number of acute and chronic medical and surgical beds (including 150 beds in Mental Wards) being 741. The medical service to the adjoining Children's Homes is performed by the Institution Medical Staff. The Institution is a recognized major Training School for Nurses and Pupil Midwives, to whom the Medical Staff are required to give lectures, and is equipped with modern Theatre X-ray and Electro-Medical appliances. The Medical Staff comprises four whole-time Resident Officers, with visiting Medical, Surgical, Aural, and Ophthalmic Consultants, Radiologist, Pathologist.

The salary assigned to the office is £400 per annum, with board and residence, and the appointment will be subject to termination by one month's notice on either side.

Applications, accompanied by copies of three testimonials of recent date, should be delivered to the undersigned not later than first post on Tuesday, March 26th. Applicants should state age, particulars and dates when taken of qualifications or degrees held, and full details of experience since qualifying.

Union Offices, Stoke-upon-Trent. March 14th, 1929.
T. WOOD, Clerk to the Guardians.

Stoke and Wolstanton Union.

SECOND ASSISTANT RESIDENT MEDICAL OFFICER (Male).

Applications are invited for the appointment of Second Assistant Resident Medical Officer (*male*) at the London Road Institution of this Union.

Salary £200 per annum, with board and residence. The period of the appointment will be limited to one year in the first instance, subject to termination by one month's notice on either side.

The accommodation at the Institution is approximately 1,154 beds, including 590 hospital beds and 150 in Mental Wards. The Hospital is a recognized Training School for Nurses.

Applications, stating particulars of qualifications or degrees held, the date thereof, when taken, and experience since qualifying, together with copies of three testimonials of recent date, should be delivered to the undersigned not later than first post on Tuesday, March 26th.

Union Offices, Stoke-upon-Trent. March 14th, 1929.
T. WOOD, Clerk to the Guardians.

Borough and Port of Poole.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the above post from registered medical practitioners (*male*) possessing a Degree or Diploma in Public Health. Preference will be given to candidates with at least three years' Public Health work subsequent to qualification. The duties will include School Medical and Port Sanitary work.

The salary is at the rate of £600 per annum. The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination.

Forms of application and terms of appointment can be obtained from the undersigned, to whom applications, together with copies of not more than three recent testimonials, must be sent not later than April 13th.

Canvassing, directly or indirectly, will be

CHARLES LISBY, Town Clerk.

March 18th, 1929.

Administrative County of SOUTHAMPTON.

COUNTY MEDICAL OFFICER OF HEALTH.

The Hampshire County Council invite applications for appointment of County Medical Officer of Health from persons legally qualified for the practice of medicine, surgery, and midwifery, and registered in the *Medical Register* as holders of a Diploma in Sanitary Science, Public Health or State Medicine, under Section 22 of the Medical Act, 1886, and of an age not exceeding 45 years at the date of application. The post is established for purposes of superannuation.

The person appointed will be required to devote the whole of his time to the duties of his office and not to hold any other appointment or engage in private practice.

He will receive a salary of £1,250, payable monthly, and all sums by way of fees or otherwise received by him will be paid over to the County Fund.

He will be provided with the necessary offices and clerical staff.

Applications on a prescribed form (which with further particulars of duties and conditions of appointment may be obtained from me), addressed to me and endorsed "County Medical Officer," must be delivered at the Castle of Winchester on or before April 20th.

Canvassing, either directly or indirectly, is prohibited and will disqualify.

The Castle, Winchester. March, 1929.
F. V. BARBER, Clerk of the County Council.

Liverpool Port Sanitary AUTHORITY.

ASSISTANT PORT MEDICAL OFFICER.

The Corporation of the City of Liverpool, as Port Sanitary Authority, require the services of an Assistant to the Medical Officer of Health, whose duties will be in connection with the Tidal Inspection of Vessels, the Medical Inspection of Aliens, and such other duties as may from time to time be assigned to him.

The salary will commence at £700 per annum, increasing to £800 per annum by annual increments of £50.

Candidates must possess a registrable Medical and Surgical qualification, and should hold a Diploma in Public Health, and their age must not exceed 35 years.

The person appointed will require to devote whole-time service to the duties specified, and will be subject to the Superannuation provisions of the Liverpool Corporation Act, 1921.

Canvassing of members of the Council is strictly prohibited.

Applications, stating age, qualifications, and past experience, accompanied by copies of recent testimonials, should be addressed to the Chairman of the Port Sanitary and Hospitals Committee, under cover to the undersigned, and delivered not later than April 5th.

Envelopes to be endorsed "Assistant Port Medical Officer."

Municipal Buildings, Liverpool. March 16th, 1929.
WALTER MOON, Town Clerk.

County of the Isle of Ely.

APPOINTMENT OF COUNTY MEDICAL OFFICER OF HEALTH AND TUBERCULOSIS OFFICER.

The County Council invite applications for the post of County Medical Officer of Health and Tuberculosis Officer.

The salary will be £900 per annum, together with the repayment of travelling expenses according to the County Council's scale, and the appointment will be terminable by three months' notice in writing on either side.

Office accommodation and staff will be provided by the Council.

The officer appointed will be responsible for the organization and administration of the whole of the health work under the County Council, and he must have held House appointments in a Chest Hospital for at least six months or have had special experience in the diagnosis and treatment of tuberculosis.

Special practical experience in Bacteriology and in the diagnosis and treatment of tuberculosis in sanatoria or otherwise, and in the administration of a tuberculosis dispensary, will be deemed additional qualifications. He will also be required to enter into a covenant not to engage in medical practice within the Isle of Ely for a period of five years after the termination of his engagement.

Applications, with copies of not more than three recent testimonials, must be forwarded to the undersigned before April 13th, on a form containing conditions of appointment, which may be obtained from the undersigned.

County Hall, March 16th, 1929.
C. E. F. COPEMAN, Clerk of the County Council.

Borough of Keighley.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The Keighley Borough Council require the services of an Assistant Medical Officer of Health and Assistant School Medical Officer at an inclusive salary of £600 per annum.

Candidates must be registered medical practitioners of at least three years' standing, and hold the D.P.H. or equivalent qualification, and also have practical experience in the duties of a School Medical Officer and Maternity and Child Welfare. Experience in Refraction, Ultra-violet Light, and Orthopædics will be considered an additional qualification.

The candidate appointed must devote his or her whole time to the duties of the office, and he or she will not be allowed to engage in private or consulting practice. The candidate will be required to reside in the Borough of Keighley.

Applications upon the prescribed form, which may be obtained from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), must be sent to me on or before April 9th, endorsed "Assistant Medical Officer."

The appointment will be determinable by three months' notice on either side.

Canvassing, either directly or indirectly, will disqualify.

Town Clerk's Office, Keighley. March 19th, 1929.
S. WALKER, Town Clerk.

Parish of St. Pancras.

GUARDIANS OF THE POOR.

The Guardians of the Poor of the Parish of St. Pancras invite applications from duly qualified candidates for the joint appointment of JUNIOR ASSISTANT MEDICAL SUPERINTENDENT of the St. Pancras Hospital and JUNIOR ASSISTANT MEDICAL OFFICER of the St. Pancras House, adjacent, with salary of £350 per annum, together with residential allowances, subject to deductions under the provisions of the Poor Law Officers Superannuation Act, 1896.

Candidates must be registered medical practitioners, qualified by law to practise both Medicine and Surgery in England and Wales.

For details as to duties, hours and off-duty time apply to the Medical Superintendent of the St. Pancras Hospital, 4, King's Road, N.W.1.

Application to be made upon forms to be obtained at my office, and selected candidates will be informed when and where they may attend a meeting of the Guardians.

Guardians' Offices, Town Hall, Pancras Road, N.W.1. March 15th, 1929.
B. CHAPMAN, Clerk to the Guardians.

Lincoln. ARTHUR MOORE,
March 8th, 1929. Secretary-Supt.

Hendon Urban District Council.

COMBINED POST OF RESIDENT MEDICAL OFFICER AT THE ISOLATION HOSPITAL AND ASSISTANT MEDICAL OFFICER FOR GENERAL PURPOSES.

Applications are invited for the above post.

The successful candidate will be required to reside at the Isolation Hospital (at present under construction) and to perform the duty of Resident Medical Officer, together with other duties in connection with the Council's Maternity and Child Welfare and School Medical Services, and generally to assist the Medical Officer of Health.

Candidates must possess a Public Health qualification and should have had Fever Hospital experience.

The salary is £500 per annum, rising by annual increments of £25 to £600 per annum, with board, lodging, and laundry. If the officer appointed takes up duty before the Hospital is completed an allowance at the rate of £150 per annum will be made in lieu of board and lodging, etc.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The successful candidate will be required to pass a medical examination.

Applications, on forms to be obtained from the undersigned, together with copies of not more than three recent testimonials, to be sent to the undersigned not later than April 6th.

Dated this 4th day of March, 1929.

Town Hall, Hendon, N.W.4. LEONARD WORDEN, Clerk to the Council.

Hendon Urban District Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the above post.

The duties will be mainly in connection with the Council's Maternity and Child Welfare and School Medical Services, but may include other *duties under the direction of the Medical Officer* of Health.

Candidates must possess a Public Health qualification.

The salary is £600 per annum, rising by annual increments of £25 to £700 per annum.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The successful candidate will be required to pass a medical examination.

Applications, on forms to be obtained from the undersigned, together with copies of not more than three recent testimonials, to be sent to the undersigned not later than April 6th.

Dated this 4th day of March, 1929.

Town Hall, Hendon, N.W.4. LEONARD WORDEN, Clerk to the Council

Borough of Bexhill.

MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified gentlemen for the appointment of Medical Officer of Health of the Borough, subject to the provisions of the Public Health Officers Act, 1921, and the Sanitary Officers Order, 1926.

The gentleman appointed will be required to perform all the duties imposed on a Medical Officer of Health, to act as School Medical Officer, and to carry out all such duties as the Council, with the consent (if necessary) of the Minister of Health, may from time to time direct. He must reside in the Borough and devote all his time to the duties of the office, and must not engage in private practice.

The salary to cover *all the duties* specified above will be £800 per annum inclusive.

Applications, stating age, experience, etc., accompanied by copies of not more than three recent testimonials, should reach the undersigned not later than April 6th, endorsed "Medical Officer."

Town Clerk's Office, Bexhill March 19th, 1929. S. J. TAYLOR, Town Clerk.

City and County of Newcastle-upon-Tyne.

CITY HOSPITAL FOR INFECTIOUS DISEASES.

RESIDENT MEDICAL ASSISTANT (Male).

Wanted immediately, a Resident Medical Assistant (male) who holds a registrable qualification in Medicine and Surgery (and preferably also in Public Health), and possesses a practical knowledge of Bacteriology.

Salary £350 per annum, *with board, lodging,* etc.

Applications, stating age, qualifications, and previous experience, to be forwarded with copies of not more than three recent testimonials to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

March 19th, 1929.

County Council of Durham.

DISTRICT TUBERCULOSIS MEDICAL OFFICER.

The County Health Committee invite applications for a District Tuberculosis Medical Officer, at a commencing salary of £600 per annum, rising by annual increments of £25 to £650 per annum. Travelling expenses will be paid by the County Council.

The appointment will be held subject to three months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered medical practitioner between the ages of 25 and 45 years, must devote the whole *of his time to the duties of the office,* and must not engage in private practice.

(2) He should have held a House appointment for at least six months in a General Hospital and have had practical experience in the treatment of tuberculosis in sanatoria and otherwise.

(3) He will be attached to the County Health Department, and will, subject to the directions of the County Medical Officer, be under the control of the Central Tuberculosis Medical Officer.

(4) He will be required to reside in his Dispensary area, or such other centre as required by the Council.

(5) *He will be required to carry out the duties* of a District Tuberculosis Medical Officer.

(6) He must be prepared, if called upon, to act as Locum Tenens to other members of the Medical Staff of the County Medical Officer

(7) The holding of a Diploma in Public Health, and practical experience in bacteriological laboratory work, will be deemed additional qualifications for the post.

The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, endorsed "District Tuberculosis Medical Officer," with copies of not more than three recent testimonials, must be forwarded on or before April 5th next to the County Medical Officer, Shire Hall, Durham, from whom forms of application can be obtained.

Shire Hall, Durham. March 18th, 1929. HAROLD JEVONS, Clerk of the County Council.

Cardiff Union.

ASSISTANT MEDICAL OFFICER.

The Guardians of the Cardiff Union require a THIRD ASSISTANT RESIDENT MEDICAL OFFICER (male or female) for the City Lodge Institution, who must devote the whole of his or her time to the duties, reside in the Institution, and (subject to the orders of the Guardians) act under the direction of the Medical Officer.

The qualifications, conditions, and duties of the appointment, which will be for six months, but renewable if the Guardians see fit, are prescribed by General Orders of the Ministry of Health, and are further defined in Rules adopted by the Guardians, a copy of which (and any *other information desired) may be obtained from* me. One duty will be to give such lectures to the Nurses as may be required.

The salary will be at the rate of £150 a year, with rations, apartments, attendance, and washing, subject to the provisions of the Poor Law Officers Superannuation Act, 1896, for which the present value of emoluments is fixed at £134 10s. a year

Assistant Medical Officers are liable to be called upon by Justices to examine and certify alleged Lunatics, for which fees are payable

Applications, on forms to be obtained from me, must reach me by 10 a.m. Monday, April 8th.

Direct and indirect canvassing is prohibited.

R. STEPHENSON.

11, Park Place, Cardiff. Clerk.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3545 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. LONDON, WEST-END.—PARTNERSHIP.—A one-fourth or one-third share is for disposal in an old-established good-class non-panel, non-dispensing Practice. Net income of share £1,120. Fees one guinea upwards. Very little midwifery from 31 guineas. Suitable flat available for bachelor, or if married purchaser could choose his own place of residence. Premium for one-fourth share £2,250.
2. PARTNERSHIP.—SOUTH COAST.—In a popular and favourite *watering-place*, the third share (to commence) of an old-*established* mixed-class Practice, offering great scope for increase, is for disposal. Cash receipts nearly £1,900 p.a., including panel (increasing) of over 1,150. Visits 3/6 upwards. About 30 cases of midwifery. Eight-roomed house, with garden. Price for freehold £1,450, of which at least £1,000 can be obtained on mortgage. Premium 2 years' purchase.
3. SOUTH OF ENGLAND.—In a pleasant town (pop. 11,000) within 5 *miles of favourite watering-place*, old-established *mixed-class* and increasing PRACTICE worth nearly £1,300 last financial year, including transferable appts. and panel of 880. Excellent family residence, standing in its own grounds (tennis court, flower garden, etc.), with ample accommodation. Held at present on lease (2½ years to run) at £90 p.a., and can eventually be bought for £1,700 or less. Premium £2,040, to include drugs, fittings, some furniture, etc.
4. PARTNERSHIP.—SOUTH OF ENGLAND.—The two-fifths share (*producing an income of about £1,750 p.a.*) can be acquired by a suitable gentleman in an old-established connection situated in an attractive town near the sea. Appts. and panel held. Visits 5/- upwards, medicine extra. Very little midwifery. Nice house available, held on short lease, but can be purchased. Excellent educational facilities, and sport of all kinds. Moderate premium accepted.
5. SOUTH-WEST OF ENGLAND.—PARTNERSHIP.—A one-half share in a very old-established Practice situated in an attractive small town, amidst *beautiful surroundings, and within easy reach of the Coast*. Gross cash receipts for the past year over £2,900. Panel of 1,218, which, together with appts., brings in about £900 p.a. Moderate expenses. *Visits 2/6*, plus mileage and medicine 2/6 and 3/6 extra. Very suitable house, with 3 reception, 4 bedrooms, and usual offices. Garden. Price for freehold £750, of which £350 on mortgage. Premium 2 years' purchase.
6. PARTNERSHIP.—SIX MILES NORTH-EAST OF LONDON.—Third Partner required in very old-established mixed-class and increasing Practice situated in populous suburb. Receipts last year nearly £2,800, including appts. (£95) and panel of 3,370. Visits 2/6 and 3/6. Very little midwifery. Good house available (professional rooms, 2 sitting, 3 bedrooms, dressing and bathrooms, etc., garden and garage) on rental at £50 p.a. Premium 2 years' purchase. Excellent prospects of increase.
7. LONDON, WEST.—PARTNERSHIP.—A half share in an old-established mixed general Practice. Average income for the last three years about £4,000. Panel of 3,250. Fees 2/6 to 7/6, visits 3/6 to 10/6, and a few at 21/-. About 30 midwiferies at from 3 to 10 guineas. Convenient house in good position. Held on lease (with no ground rent) with 25 years to run. Price £1,650. Premium £4,000. Must be Scotch or English.
8. CORNISH RIVIERA.—*In a small but rapid*
6,000—6,000) on the Coast, an old-estab. P
year over £1,000, including appts. and pane
tion weak. *Delightful residence, standing in own grounds of 1¾ acres* (croquet and tennis lawns, etc.) and eminently suitable for Resident Patients, which Vendor has been in the habit of taking. Contains professional rooms, 4 reception, 9 bedrooms, 2 bathrooms, etc. Water and electric light. Garage. Price for freehold £4,000. Prem. £1,500.
9. HOME COUNTIES.—PARTNERSHIP.—A three-eighths share (with increase later) in a very well-established mixed-class Practice, producing about £3,000 p.a. (including panel of 1,500), situated in a desirable *residential district*. Fees from 3/6 to £1/-. Suitable *accommodation* available. Ingoing Partner should be between 30 and 35, and preferably hold University degree. Premium 2 years' purchase.
10. LONDON, NORTH.—PARTNERSHIP.—A one-third share, to commence with, in a very old-established mixed general Practice. Income approximately £3,400, including appts. and panel of over 3,000. Surgery fees 2/- upwards, visits 3/- upwards. If unmarried, ingoing Partner could reside with senior; otherwise, suitable house available. Premium 2 years' purchase, half by arrangement.
11. LONDON, SOUTH-WEST.—Within three miles of Charing Cross.—PARTNERSHIP.—A half share, with succession to the whole in about two years, in a very *old-established non-panel Practice*, held by Vendor 26 years. Steady average income of £2,300. Surgery fees 2/6 and 3/6, visits mainly 5/- and 7/6. Very little midwifery. Good house, in main road, with garden. Held on lease, with nearly 15 years to run, at a rental of only £55 p.a. Premium 2 years' purchase. Very good scope for increase.
12. KENT.—COUNTRY PRACTICE, within six miles of the Coast.—Old-established mixed general Practice. Income for past twelve months £1,672, including appts. about £60, and panel of over 700. Fees 3/6 to 21/-. Not much midwifery 2 to 7 gns. Good house, with 2 reception, 5 bedrooms, etc. Large garden and orchard. Garage for 2 cars. Price for freehold £1,350. Sport of all kinds, and schools within reach. Premium £2,250.
13. PARTNERSHIP.—SOUTH COAST.—In a fashionable watering-place, the two-thirds share is for disposal in a mixed Homœopathic and Allopathic (roughly half and half) good-class non-dispensing, non-panel connection, in which there is a certain amount of surgery, and ingoing partner should be an operating surgeon. Receipts average over £3,600 p.a. Fees up to 10/6. Very little midwifery. Large and suitable maisonette available, with ample accommodation, in excellent position. Garage. Rent, on lease, £250 p.a. Premium for share 1½ years' purchase.
14. PARTNERSHIP.—Within 3 miles North-West of Charing Cross.—The half share of an old-established middle and working-class Practice, averaging about £2,100 p.a., including panel of 1,300. Visits 2/6 to 10/6. House contains, in addition to professional accommodation, 2 reception, 2 bedrooms, bathroom, kitchen, etc. Small garden. Net rental, on lease, about £60 p.a. Premium 2 years' purchase.
15. HAMPSHIRE.—PARTNERSHIP.—Third share of an old-established unopposed Country Practice, in very pretty district within a few miles of a large town, and producing nearly £2,500 p.a., including *appointments £130, and panel of 1,520. Visits 5/6 to 21/-. Mids.* 2 to 10 gns. Large house (having eight or nine rooms, with garden, etc.), which must be purchased, or ingoing partner could reside in rooms until a smaller one becomes available. Premium 2 years' purchase, half down and balance in 12 or 18 months.
16. KENT.—Old-established Country PRACTICE, situated in very favourite locality within 5 *miles of the coast. Income* for past 12 months £1,030. Surgery fees 3/6 upwards, visits 5/- to 21/-. Poor Law appt. and panel of about 380. Attractive commodious house, with separate professional rooms. Small garden. Price £1,800. Premium £1,500.
17. HOME COUNTIES.—GROWING COUNTRY DISTRICT.—Old-established mainly middle and working-class PRACTICE. Income for the last year £550, with ample scope for increase. Fees 2/6 to 7/6. Little midwifery. Go £1,500, part on *mortgage*. Sport of all kinds ons advantageous. Premium £850.
18. LONDON, centrally situated *mixed general* PRACTICE. Income for the immediate past year *£3,500, including* panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Long introduction.
19. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing *mixed-class PRACTICE, averaging about £3,000* p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 5/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, *part* by arrangement if necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
20. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. *Patients*—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of *Hospital* (nearly 300 beds) and successor will be appointed.
21. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra Mids. (discouraged) 2 to 5 *guineas*. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, *and good* professional rooms and usual offices. Hot water supply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
22. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good and commodious house, with nice garden. Can be rented on lease at £75 p.a. Garage for 3 cars. Premium 1½ years' purchase, part by instalments.
23. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed *general PRACTICE, situated in pleasant district within easy reach of* town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of about 2,200. Fees 2/6 to 7/6. Midwifery from 5 gns. (about 40 cases yearly). *Moderate* expenses. Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden, Brick-built garage. Premium £4,500.

REQUIRED.—MEDICAL OFFICER for Cable Company. Salary £500 p.a., all found. Three years' engagement. First-class out and home. Must be of British nationality and under 30 years of age. Sail end of March. Personal application preferred.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

'BYNIN' AMARA

(TRADE MARK)

A Powerful Tonic and Hæmatinic

'Bynin' Amara is of special value in influenzal conditions and in the marked asthenia and nervous depression which are prominent features of the post-influenzal state. A course of 'Bynin' Amara whenever there is any indication of lowered resistance is a valuable safeguard against infection.

It has important advantages over Easton's Syrup on account of its basis being 'Bynin' Liquid Malt *in the place of syrup*. The 'Bynin' Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

In bottles at 3/6, 6/6 and 12/-

WHAT IS AN IDEAL APERIENT?

The obvious answer is that "It all depends." Certain qualities and properties are always undesirable; others are nearly always desirable. Nine times out of ten we look for an aperient that

1. Is harmless; even when taken in unnecessarily large doses.
2. Is pleasant to the taste; yet contains no sugar or flavouring matter.
3. Is pleasant and thorough in action; yet does not cause pain, nausea, or straining.
4. Does not irritate the epithelial lining, or disintegrate the protective mucus.
5. Acts on excess hydrochloric acid as a neutralizer; yet does not make the urine alkaline.
6. In no way upsets mineral metabolism, and is free from the mineral purgative salts.

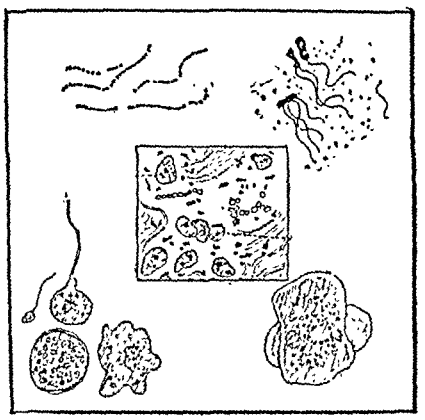
All these qualities and properties co-exist in Eno's 'Fruit Salt," an effervescent antacid aperient that has enjoyed the confidence of the medical profession for more than half a century.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy, or Household size as required). "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series

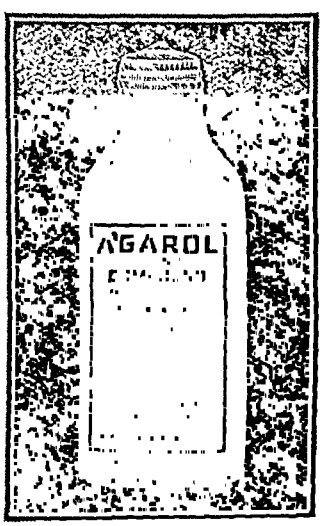
J. C. ENO LTD., 160, PICCADILLY, LONDON, W.1

When the Colon Bacilli Revolt



WHEN the normally non-pathogenic colon bacilli rebel under the influence of foreign invaders or because of the putrefaction and toxæmia resulting from constipation and fæcal impaction, the consequences may be grave in the extreme.

The logical treatment is obviously preventive. In all cases of chronic constipation, incipient stasis or fæcal impaction, and in certain forms of intestinal toxæmia, prompt and efficient evacuation, followed by gradual resumption of normal bowel action, will be obtained by the use of AGAROL Brand Compound, *the original agar-agar emulsion.*



A generous trial quantity sent on request

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* mineral Oil — Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

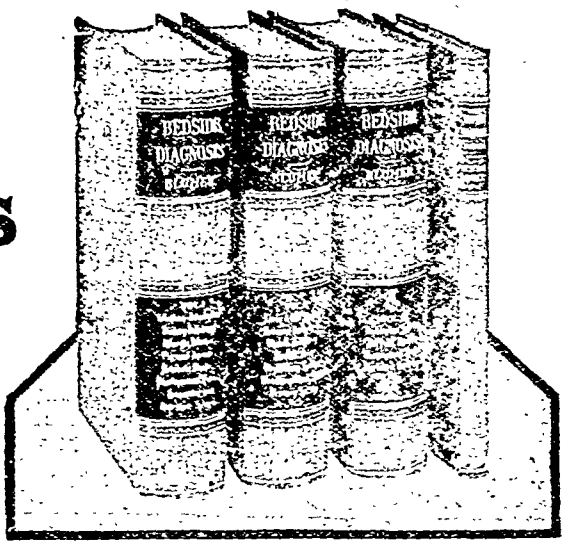
Blumer's Bedside Diagnosis



Read what the LANCET says:

"THE TITLE OF THIS WORK is designed to call attention to the fact that it is an attempt to emphasise the importance of diagnosis without extensive laboratory equipment. Many patients still have to be treated in their own homes, where facilities for diagnosis are limited to clinical examination, with only such aids to the senses as the stethoscope and the thermometer. The authors hold that more accurate aids will never replace the older and simpler methods, while not minimising the importance of any kind of diagnostic test when it is available. Deliberately, then, they have omitted details of laboratory procedures while indicating their value, especially when combined with clinical observation.

". . . the book is well bound, the print is excellent, and the illustrations carefully chosen and well reproduced. Not only is each volume indexed, but a separately bound index to the whole three volumes is provided, so that fruitless searching in the wrong volume can be avoided.

"The physician will find it hard to get a finer book."

Three octavo volumes, totalling 2,820 pages, with 890 illustrations. Edited by GEORGE BLUMER, M.D., David P. Smith Clinical Professor of Medicine, Yale University Medical School. Per set, Cloth, £6 15s. net. *Index volume free.*

Babcock's Surgery

IMMEDIATELY SUCCESSFUL

Dr. Wayne Babcock's book is complete. It contains a full discussion of general surgery, minor surgery, major surgery, the diagnosis of surgical conditions and their treatment—medical, surgical, or both, as indicated. The 1,050 illustrations, 9 in colours, are nearly all original and have been specially drawn under Dr. Babcock's supervision. They are clear and instructive. Frequently the right way is contrasted with the wrong way of doing things and points of particular importance are indicated.

Octavo of 1,367 pages, with 1,050 illustrations, 9 in colours. By W. WAYNE BABCOCK, M.D., Professor of Surgery, Temple University, Philadelphia. Cloth, 45s. *net.*

DeLee's Obstetrics

FIFTH EDITION

Both text and illustrations received careful revision in the preparation of this Fifth Edition. The greatest increase was made in those sections devoted to the work of the general practitioner. Dr. DeLee added many new illustrations, and re-wrote completely many of the chapters.

Octavo of 1,140 pages, with 1,128 illustrations, 201 in colours. By JOSEPH B. DELEE, M.D., Professor of Obstetrics at the Northwestern University Medical School, Chicago. Cloth, 55s. net.

Foster's Examination of Patients

SECOND EDITION

In addition to a record of all the important advances, this new (2nd) edition contains new—brand new—sections on the febrile diseases, the anemias, the endocrines, the muscles, joints, bones, and vessels, and a greatly expanded section dealing entirely with tests.

By NELLIS B. FOSTER, M.D., Associate Professor of Medicine, Cornell University College of Medicine. Octavo of 253 pages, with 70 illustrations, a number in colours. Cloth, 21s. net.

Graves' Gynecology

FOURTH EDITION

A new work—that's what this edition really is, because the revision was so extensive that it amounts to re-writing. Whole sections have been cut out, others have been completely re-written, new chapters have been inserted, old material that was retained received new form because of omissions, corrections, and additions.

Octavo volume of 1,016 pages, with 562 illustrations, 126 in colours. By WILLIAM P. GRAVES, M.D., Professor of Gynecology at Harvard Medical School. Cloth, 48s. net.

W. B. SAUNDERS COMPANY Ltd. 9, Henrietta Street LONDON, W.C.2

LAST DAY for SUBSCRIBERS' PRICE at 17/- net is APRIL 13th.

NEARLY READY. 47th YEAR. Many Text Illustrations and 71 Plain and Coloured Plates. **20/- net,** postage 9d.

AN INDEX OF SYMPTOMATOLOGY

By Twenty-six Distinguished Contributors,

Edited by

H. LETHEBY TIDY, M.A., M.D.Oxon., F.R.C.P.Lond., *Asst. Phys., St. Thomas's Hospital; Con. Phys., Royal Northern Hosp.*

This book is intended to provide an account of the symptomatology of diseases. The general object has been to give a clear and reasonably full description of the clinical manifestations of each disease, without dwelling unduly on minor complications and variations.
"Should help considerably in the solution of difficult diagnostic problems. The articles, which cover all branches of medicine, surgery, gynæcology, and the specialities, are tersely written and well up to date . . . a volume worthy of the series to which it belongs."—B.M.J.

[Catalogue free.] **London: SIMPKIN MARSHALL Ltd.**

THE CLINICAL JOURNAL.

6d. An Illustrated Weekly Record of CLINICAL MEDICINE and SURGERY. **6d.**

"I read the 'Clinical Journal' regularly, and always with interest and instruction."—SIR JOHN BLAND-SUTTON.
". . . my weekly perusal of the 'Clinical Journal' was a very important factor in my medical education."
—SIR THOMAS HORDER.
***Special Leaflet, with selected list of articles and other details, on application.
ANNUAL SUBSCRIPTION (commencing at any date), 26s.; Six Months, 13s. 6d.; Three Months, 7s., post free.

London: H. K. LEWIS & CO. Ltd., 136, Gower Street, and 24, Gower Place, W.C.1.

JUST PUBLISHED. FOURTH EDITION. Crown 8vo. 4s. net, postage 2d.

HYPNOSIS AND SELF-HYPNOSIS.

METHODS AND USES OF

By Bernard Hollander, M.D. **6s.**

Dr. Hollander's new book is the result of thirty years' experience of experimental hypnosis and hypnotic treatment, and contains directions how to apply hypnotism for the treatment of functional nervous and mental disorders and moral failings, as well as detailed evidence of phenomena throwing light on the mysteries of thought-transference, clairvoyance, etc.

GEO. ALLEN & UNWIN, Museum Street, London, W.C.1.

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

FAMILY  TRADITION

"Passing the Torch" is no mere byword in the case of many members of the Medical Profession who can lay claim to many preceding generations of practitioners.

Such Family Tradition is proudly acknowledged by the House of Salt, which, now in its FIFTH GENERATION, has built up a unique reputation for its hundred and thirty-five years of practical co-operation with Modern Surgery in supplying every type of Surgical Appliance specially made with absolute precision to each individual case and strictly according to the attendant practitioner's prescription.

It is largely owing to our experience in interpreting medical requirements that our unique Guarantee is rarely taken advantage of—yet it is always satisfactory to both practitioner and patient to know that our "no-obligation" clause gives such adequate safeguard.

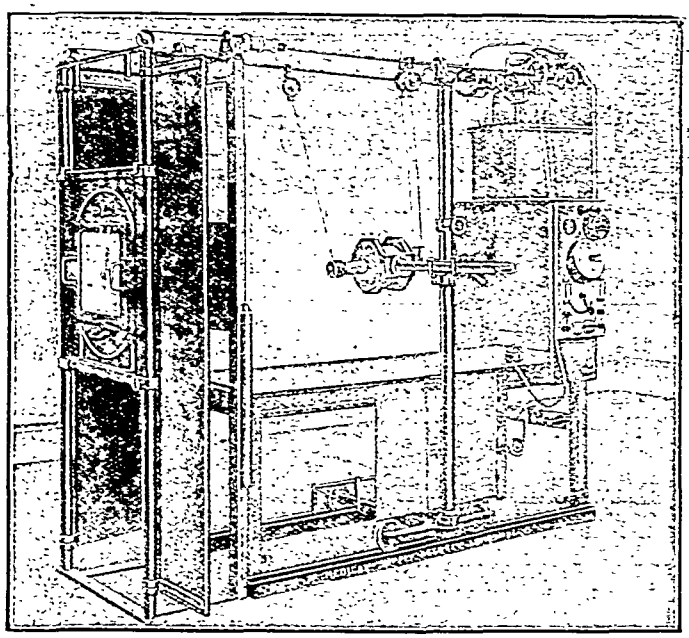
N.P.L.



THE CERTIFICATED APPARATUS.

UNIVERSAL X-RAY APPARATUS

"You switch on—we do the rest!"

This apparatus is exactly what its name implies—a universal X-ray Apparatus. It provides for radiography (general, dental, compression); radiotherapy; horizontal screening; vertical screening. It is the ideal all-round X-ray equipment for hospital, clinic, or private practice.

The UNIQUE TECHNIQUE DIRECTOR has revolutionised radiography. By the turning of a knob, it gives automatically every factor required for producing successful radiograms with certainty. These factors obtained, the setting of the controls is the essence of simplicity.

The N.P.L. APPARATUS GIVES FULL PROTECTION. It is unconditionally certificated by the National Physical Laboratory as complying with the recommendations of the X-ray and Radium Protection Committee.

The N.P.L. Universal X-Ray Apparatus is extremely compact. It occupies a floor space of only 7 ft. 6 in. × 2 ft. 8 in.

Price, complete with all Accessories for Alternating Current - £300

" " " " Direct Current - - £345

Being entirely of British manufacture, this apparatus is free of importation duty.

Intestinal Disinfection

MUCOUS AND OTHER FORMS OF COLITIS

CONDITIONS of Colitis occur at all ages, and lead to much suffering, ill-health and chronic invalidism. They are caused by a great variety of bacteria, which, owing to a loss of resistance on the part of the mucous membrane of the colon, maintain a chronic infection, with inflammation of this portion of the intestinal tract.

Vaccine therapy is frequently tried in this condition with disappointing results, as it is pure chance if the causative organism is isolated from the host of bacteria present.

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present. Kerol is the one substance which possesses this power, and its administration has cured many a case of mucous colitis.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Recent Laboratory Work in Connection with Lysolats

The searching tests to which the solid form of lysol has been subjected have confirmed the favourable medical opinion of the bactericidal value of Lysolats.

Experiments have been carried out under the Rideal-Walker and Martin-Chick technique by such authorities as the Royal Institute of Public Health Laboratories, London, the Pathological Laboratories, Harley Street, W., and the Clinical Research Laboratories, Adelphi, W.C.

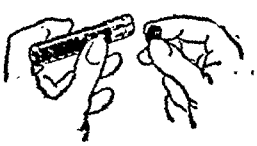
Abroad, similar tests have been made by the Pasteur Institute, Paris, the Microbiological Laboratories of the University of Nancy, and Professor Huynen of the State Veterinary University of Brussels.

It has been determined that a 1 per cent. solution of Lysolats will arrest the development of most pathogenic organisms in 2 seconds and will completely destroy them within 40 to 50 seconds.

A comparative test in different dilutions of Lysolat and Carbolic Acid on the following organisms—B. Pyocyaneus, B. Bang, B. Typhosus, B. Coli, B. Pneumococci, B. Staphylococci—shows that the bactericidal power of Lysolats is 20 times more efficient than that of ordinary Carbolic Acid.

Lysolats

PATENT 118667 (LYSOL TABLETS)



For Personal Use by Medical Men.

Many doctors now use Lysolats when washing their hands. One tablet rubbed between the palms with plenty of water is a valuable safeguard.

* * *

Lysolats are packed in handy tins which are particularly suitable for carrying in the pocket. The tins contain [illegible] tablets and 2/- and 5/- respectively. There are also tins of 1,000 tablets.

* * *

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney Street, London, S.E.1.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

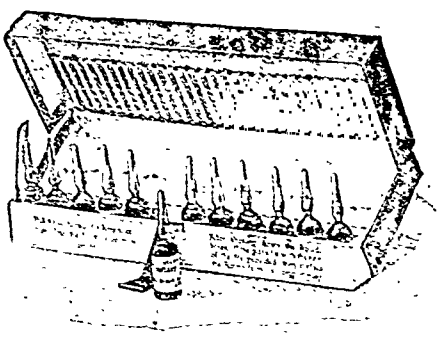
In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

PITUITARY EXTRACT B.D.H.

(Posterior Lobe)



Issued also in boxes containing 100 ampoules specially for hospital use

From the time it was first issued for medical use Pituitary (Posterior Lobe) Extract B.D.H. has been standardised for two entirely different effects as follows:

Its action in the contraction of the uterine muscle

Its effects upon blood pressure

Pituitary (Posterior Lobe) Extract B.D.H. is entirely British made; it is manufactured in the B.D.H. laboratories from carefully collected and dissected glands, and every batch is guaranteed to be of uniform activity.

FELLOWS MEDICAL MANUFACTURING CO., Inc.
26 Christopher Street, New York, U. S. A.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

DINNEFORD and Co. LTD.

WRIGHT'S LYSOL

BRITISH MADE :: :: BRITISH OWNED

The quality of WRIGHT'S LYSOL has never been questioned

It is safe to prescribe Wright's Lysol — safe because you know that your patients will then get a pure and highly refined Lysol, controlled by the Rideal-Walker test. Wright's contains no free alkali — does not sting or irritate — gives certain results. It is widely used by the profession; Hospitals and Nursing Homes prefer it. Tell your patients always to say "Wright's" before "Lysol."

British owned and British made by the makers of the world famed Wright's Coal Tar Soap.

A handy graduated measure is provided with every bottle.

Streets 50.

For Ill Conditions of the Gastric Tract

"Alocol" is the practitioner's safeguard when alkaline medication is indicated. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia, and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place: a colloidal jelly is formed, which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

The advantages of "Alocol" are therefore manifest. It neither hinders proteolysis nor causes destruction of any food element or factor. Prolonged exhibition interferes in no way with the normal putrefactive function of the gastric juices, or with the regular processes of nutrition.

"Alocol" is regarded as a specific in the treatment of hyperchlorhydria, whilst for all forms of fermentative dyspepsias, with gastro-intestinal flatulence, acid eructations, and other symptoms common to gastric disease, its influence is beneficial to the highest degree.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

INSULIN "A.B."

TRADE A B MARK

Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.

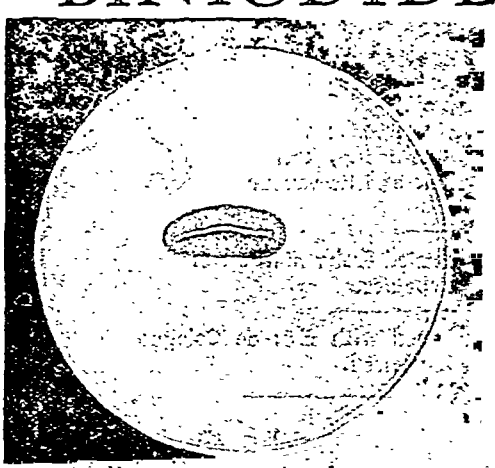
'ULTRATAN'
The LONDON HOSPITAL BINIODIDE CATGUT



(Morley's Process)

"A short length of London Hospital Biniodide Catgut was placed in agar-agar thickly sown with aerobic spores and incubated. The inhibiting action of Biniodide in the catgut not only prevented invasion but exerted a local bactericidal action in the infected agar-agar for a distance of from 5 m.m. to 9 m.m. round the ligature."

Members of the profession are invited to visit the department at the London Hospital, Whitechapel, to inspect the process of manufacture throughout.

A Sample and Descriptive Booklet will be sent post free on application to

ALLEN & HANBURYS LTD.
48 Wigmore Street, London, W 1.

The London Hospital Catgut may be obtained from all the leading Surgical Equipment Houses

For Head Colds Prescribe "Mistol"

MISTOL and the Mistol Dropper are a real advance in nose and throat therapy. Menthol, eucalyptol, and camphor are combined in a specially prepared petroleum base, which keeps these soothing and healing ingredients in direct contact with the mucous membrane for a considerable length of time.

Unlike douches, Mistol avoids any possibility of sinus trouble. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Sold in original sealed cartons containing a—

MONSOL is a highly refined and efficient antiseptic prepared from Mond Oils.

MONSOL is a practical application of four essential principles, never before combined :—

(*a*) *Germicidal Power* (*b*) *Complete Penetration*
(*c*) *Harmless to Tissue* (*d*) *Healing Action*

Thus—**MONSOL** attacks all germs, whether surface or deep seated, without irritation or injury.

MONSOL products all combine these unique properties as no other preparations can do.

BELLE VUE SPA

TREFRIW, NORTH WALES

(Railway Station Llanrwst and Trefriw)

Telephone—LLANRWST 60. Telegraphic Address—"BELLEVUE, TREFRIW."

AMBULATORY TREATMENT LTD.

THE establishment is at Trefriw village and occupies a sheltered fold of the western slopes of the Conway Valley, about 15 miles from Llandudno and 5 from Bettws-y-Coed. Its terraces and windows command the pleasant contours of the river and the hills.

Although on the fringe of the central mountain mass of Wales, its rainfall is no greater than that of London, and its climate is far milder. It is protected from all the colder winds; in winter there is rarely any frost or snow. Here, the facilities of an up-to-date nursing home have been combined with the comfort and cuisine of a charming country hotel, and a complete equipment has been assembled for the treatment of affections of the bones and joints by progressive modern methods.

The Spa is remarkable, amongst all other Spas both at home and abroad, for the strength and purity of its iron springs. The geological conditions are peculiar. The waters percolate from a mountain tarn a thousand feet above, and pass through deposits of pyrites embedded in the hills which shelter Belle Vue on the west. By taking advantage of ancient tunnellings left by a forgotten generation of miners, and only recently brought to light, it has been possible to tap the iron waters at their source, a considerable depth below the surface of the mountain side. They issue from the pyrite beds in a state of complete purity, the iron salts being entirely in that ferrous form appreciated by the physician and the pharmacist. They are secured before there has been any opportunity for oxidation to occur from exposure to the air, and oxidation is still further retarded by the presence of minute amounts of Sulphurous Oxide. For these reasons there is no contamination by admixture with even traces of ferric salts whose irritant and astringent properties are undesirable in waters intended for internal use.

The Chalybeate spring provides a ferrous water which is not only absolute in its purity, but unique in its concentration. It contains more than 3 per cent. of anhydrous ferrous sulphate. The equivalent of a Blaud's pill is to be found in less than one ounce. It affords a means of applying a natural iron therapy in which the dose of iron can be closely regulated. The patient need not imbibe a large volume of water in addition unless it should seem desirable for him to do so.

The method is proving invaluable in the secondary anæmias of rheumatic conditions; also in chlorosis, chronic septic anæmia, the anæmias which follow acute infection, and those resistant forms peculiar to protracted illness and chronic disease.

The Iron Springs at Trefriw are much stronger than any other pure ferrous waters in the British Isles. They are, in fact, twenty times as strong as the next in series. Abroad the strongest pure ferrous waters are at Ronneby, in Sweden; but these are only one-fifth as strong as those of Belle Vue Spa.

Many medical men have written about the curative properties of these ferrous waters in the early cases of arthritic origin, so-called rheumatism.

From my own observation I find that patients treated by my manipulative extension method derive great benefit, not only from drinking the waters as an addition to the extension cure, but also by the beautiful air, and last, but not least, the incentive to improve the blood supply by walking amongst the beautiful country surrounding Trefriw.

Observations on THE TREATMENT OF FRACTURES INVOLVING THE ANKLE-JOINT.*

BY

ROBERT OLLERENSHAW, M.D., F.R.C.S.Eng.,

CLINICAL LECTURER IN ORTHOPAEDIC SURGERY, MANCHESTER UNIVERSITY.

SINCE the days of Pott and Dupuytren fractures involving the ankle-joint have received much consideration, though not too much, in view of the disabilities which may follow in their train. Apart from the classical fractures, as usually described, the great importance of the anterior and posterior marginal fractures of the tibia was emphasized by Cotton in 1915,[1] and more recently by Ashurst.[2] It should always be remembered, however, that Astley Cooper described the posterior marginal fracture in 1822.

TYPES OF ANKLE FRACTURE.

Three years ago the British Orthopaedic Association, at its meeting in Manchester, discussed ankle fractures at some length, and I fear that it is not possible for anyone to break much new ground to-day. In considering my contribution to this discussion it seemed to me that an outline of the treatment adopted and the results obtained in a series of my own cases would be of most use. Beyond this, I propose to review a number of isolated cases which have offered more than the usual difficulties in their treatment. The incidence of the various types of fractures at the ankle is shown by the following summary of 100 cases radiographed at Salford Royal Hospital between December, 1927, and November, 1928.

Summary of 100 Consecutive Cases (Radiographic Findings) at Salford Royal Hospital, December 12th, 1927, to November 30th, 1928.

External malleolus	44
Internal malleolus	14
Fibula and internal malleolus and tibial epiphysis	15
Both malleoli	12
Tibia and external malleolus	2
Posterior margin fractures (with malleoli)	7
Anterior margin fractures (alone 1; with external malleolus 1)	2
Astragalus with malleolus (internal 1, external 2)	3
Cuboid with malleolus (external)	1
Total	100

You will notice the large percentage of the simpler type of isolated fracture of the external malleolus. In this connexion I would like to refer for a moment to a point in the mechanism of production of fractures of the ankle. Although, as each one of us can testify, the most usual direction for the foot to turn in an ankle "twist" is towards a varus, or inverted, position, we find that not more than 3 or 4 per cent. of fractures occur which can be described as having been brought about by a forced inversion. What is the reason? Why are 90 per cent. or more of our ankle fractures due to an abduction, or valgus, twist? I believe that many a man avoids a serious fracture because, when his ankle turns into a sudden inversion, he follows it with his body, as the wrestler is taught to do, and so takes the strain. He gives way with the force, and the strain is distributed. In the reverse position it is not possible to give way similarly, and the full straining force falls on the ankle mortise.

The proportion of external malleolus fractures in this list is very close to that shown by an earlier series of 100 fractures, collected prior to the end of 1925 in order to allow us to estimate the ultimate results. As many of you know, it is a matter of some difficulty to trace end-results in hospital cases. The poorer classes are apt to change their residences frequently and so become lost; others are too careless or too illiterate to reply to the answers on the questionary with accuracy. The registrar's office sent out 100 circulars to the consecutive cases prior to December 31st, 1925, and about 65 replies were received. Further cases, continuing the series, were then approached, and, after writing to about 150 patients, complete replies from 100 were obtained, and investigated. The following table embodies, therefore, not strictly a consecutive 100 fractures, but 100 consecutive replies. The proportions, however, fall closely into line with most other series, and I give them as representing our results.

End-results in 100 Consecutive Cases of Ankle Fracture prior to the End of 1925.

	Cases.
External malleolus	42
Returned to former work	39
Average time off work eight weeks.	
Internal malleolus	8
Returned to former work	8
Average time off work eleven weeks.	
Both malleoli, fibula and internal malleolus	35
Returned to former work	30
Average time off work nineteen weeks.	
Marginal fractures	12
Returned to former work	9
Average time off work twenty-six weeks.	
Fibula with dislocation astragalus	1
Returned to former work	1
Away from work twenty-three weeks.	
Fibula, internal malleolus, and astragalus	2
Returned to former work	2
Away from work seventeen and eighteen weeks.	
Total	100

Out of 100 cases, all varieties, there returned to original work 89 per cent. Average time off work fourteen weeks.

In our discussion in 1925, to which I have already referred, one of the speakers reported end-results and provided a series of 60 cases. These were further subdivided into Pott's fractures 20, external malleolus 14, both malleoli 8, various others 18. The first group included all cases which had a fracture of the fibula near the lower end, with displacement of the foot outwards, and some definite sign of injury to the inner ankle. The speaker found that out of his 14 cases of external malleolus fracture 14 had returned to work. A computation of 100 per cent. returns to work in this type of fracture was therefore made. Nothing approaching this recovery rate had ever been hoped for, and the speaker's conclusion was, of course, fallacious. There is no greater error than to calculate percentages on fewer than 100 cases. No one could say what would be the end of the other 86 cases still needed to complete the 100. In series of fewer than 100 only the actual figures can be accepted.

TREATMENT OF FRACTURE AT THE ANKLE.

On arriving at hospital the limb should be placed on a temporary splint for transport to the radiological department. At least two views of the fracture must be taken, lateral and antero-posterior, and the result carefully scrutinized for the less obvious displacements. The gross fractures and dislocations are easily seen, but the lesser degrees of departure from the normal must not be overlooked. With this in mind, I would like to show the radiograms of a fracture which I was asked to see recently. The patient had stumbled and twisted the foot, at the same time plantar-flexing the ankle. The practitioner in charge sent the patient for radiological examination, and with the pictures came the report: "Fracture of external malleolus. There is no displacement."

On the strength of this report the foot was not subjected to any manipulation, but was left to rest on a pillow, and massage was commenced. The ankle became more painful, and refused to allow any movement at all in the direction of dorsiflexion. I was asked to see it, and found the foot plantar-flexed, with some prominence of the

* Made in opening a discussion at the Manchester Surgical Society, February 5th, 1929.

13560]

astragalus in front. The radiogram showed quite a definite displacement forwards of the astragalus (Fig. 1). There is no doubt that had the ankle been left as it was there would have been a very tedious recovery and probably some permanent loss of ankle movement. Under gas anaesthesia I dorsiflexed the foot, with the result shown in Fig. 2. At the end of forty-eight hours the patient himself was able to perform a reasonable degree of dorsiflexion. I would therefore ask radiologists to be especially careful in their reading of the radiograms of injuries before reporting "no displacement," and particularly so if the patient is going home under the care of his general practitioner, who may be relying very largely on the radiologist's report for guidance in treatment.

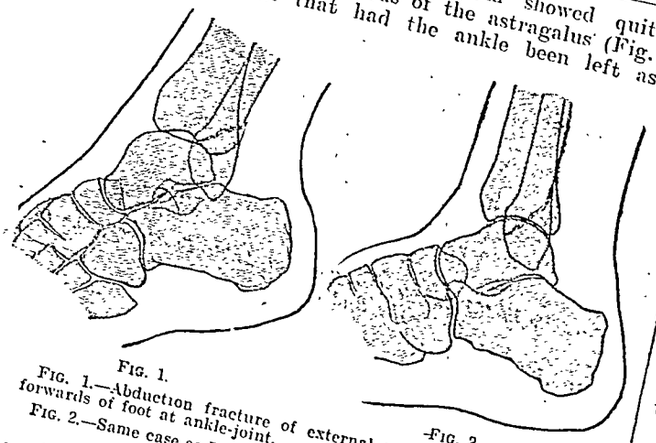

FIG. 1.

FIG. 2.

FIG. 1.—Abduction fracture of external malleolus; subluxation forwards of foot at ankle-joint.

FIG. 2.—Same case as Fig. 1; subluxation reduced.

Reduction of Displacement.

When displacements are revealed by the radiograms, those usually to be overcome are: (1) eversion of the foot; (2) backward displacement of the foot; (3) some degree of equinus; (4) separation of the tibia and fibula. As good an anatomical reduction as possible must be aimed at. It is true that good functional results are seen in which the anatomical result is imperfect, but, on the other hand, there are extremely few poor functional results where a correct anatomical reduction has been obtained. It does occasionally happen that, despite the best of treatment and the most careful reduction, the ankle remains painful. The reason is the development of a traumatic osteo-arthritis. In such a case further treatment, to which I shall refer later, will probably be required.

The displacement having been determined, a general anaesthetic is given and the calf muscles are fully relaxed by flexing the knee. The heel is grasped firmly and drawn forwards whilst the other hand fixes the lower leg. The backward displacement is completely overcome, and the ankle is then dorsiflexed with the foot inverted to approximate the astragalus and internal malleolus (Figs. 3 to 8).

Methods of Fixation.

Our most useful method of fixation is undoubtedly a plaster-of-Paris cast. In the simpler injuries, such as those of the external malleolus only, with no tendency to redisplacement, a plaster strip, as advocated by Kellogg Speed, is sufficient, alone or reinforced with a bandage circularly applied. The ambulatory plaster splint described by Delbet in 1916, consisting of two laterally placed plaster splints fixed by transverse strips to the sides of the leg at the malleoli and below the knee, is easily applied, and is much used in some hospitals. The splint was originally intended for fractures of the leg bones. The apparatus allows movement of both ankle- and knee-joints, and after a week or ten days the patients are encouraged to walk in the plaster splint. Delbet also advised its employment in ankle injuries, and reported 53 good results in 55 cases. My own experience of Delbet's splint is small but increasing, and I am sure that it is a most useful appliance. I have observed that not infrequently more than one plaster is required, and Delbet himself found that of 123 cases in which the splint had been used, 68 cases needed a second cast, 28 needed a third cast, 3 needed even a fourth cast, and only 20 cases got through on one splint.

The plaster splint which I have chiefly used extends from the toes to below the knee. It is, of course, completely unnecessary to fix the knee-joint in a fracture so low down as an ankle fracture. The cast is split laterally along both sides, so as to permit constant inspection and early massage. All the fractures of the external malleolus alone, and others which show no tendency to displacement, are given massage almost at once and are encouraged to commence active ankle movement after two or three days. The fractures which have shown a tendency to redisplacement are retained in the position of reduction for a longer period, varying with the individual case, but always a minimal one. In some few cases of severe marginal fracture with backward displacement of the foot there is difficulty in maintaining even the smallest degree of dorsiflexion after reduction. The tendo Achillis becomes tightened and the obliquity of the line of fracture allows the tibia to slip forwards again. In these circumstances a tenotomy of the tendo Achillis is an

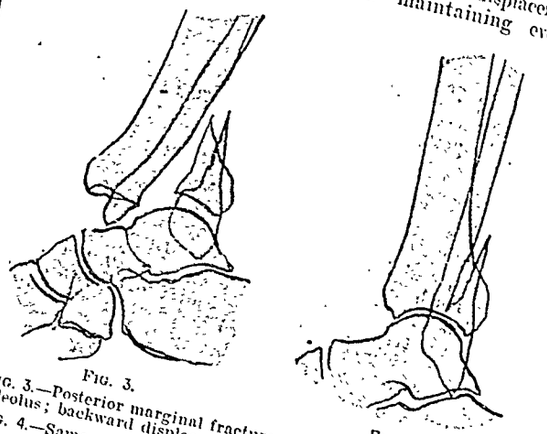

FIG. 3.

FIG. 4.

FIG. 3.—Posterior marginal fracture of tibia; fracture of external malleolus; backward displacement of foot.

FIG. 4.—Same case as Fig. 3; displacement reduced.

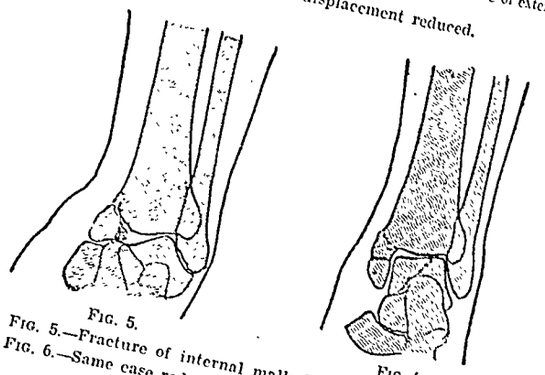

FIG. 5.

FIG. 6.

FIG. 5.—Fracture of internal malleolus and astragalus.

FIG. 6.—Same case reduced.

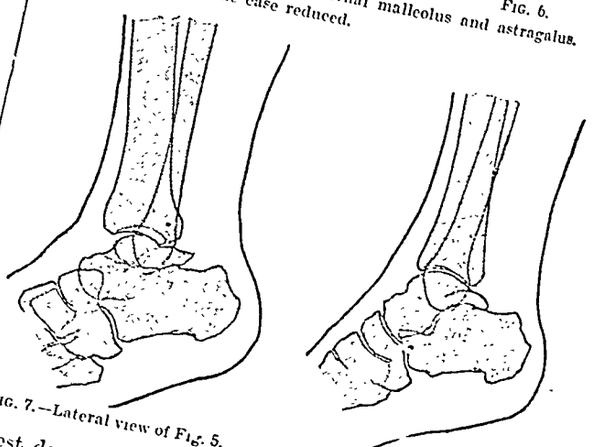

FIG. 7.

FIG. 8.

FIG. 7.—Lateral view of Fig. 5.

FIG. 8.—Same after reduction.

advantage, and I do not hesitate to perform it. In cases of severe comminution at the ankle, sometimes also further complicated by a compound wound, Steinmann's pin and direct traction on a Thomas knee splint are very valuable. After union has occurred all our ankle fractures, except those in children or a few of the more simple fractures in adults, are fitted with a wedged boot and an outside brace to prevent any tendency to valgus when weight-bearing starts.

The question as to the form of splint, however, is of small importance compared with the ability of the individual to use his appliances properly. For anyone to say that this or that splint is the only proper one to use is a mere conceit. Each one should learn to use an apparatus with which he can produce an efficient result, and strive to make his technique with his apparatus as perfect as possible.

Operative Measures.

Operative measures, in recent cases, should be adopted only if the displacement cannot be reduced satisfactorily, or if it cannot be maintained by the usual routine methods. Many have pointed out, and with good reason, the danger of using screws, plates, or other foreign bodies in the presence of a wound, but in several cases of severe displacement, with the tibia fragment projecting through the skin over the internal malleolus, I have fixed the fibula with a plate and screws, merely as a temporary measure.

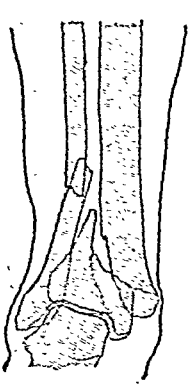

FIG. 9.

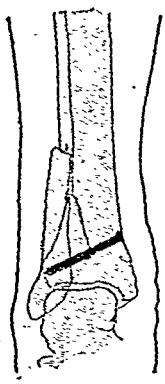

FIG. 10.

FIG. 9.—Very oblique fracture of tibia, almost compound.
FIG. 10.—Fixation by pin.

The tibial wound is cleaned or excised and the fibular wound kept completely shut off. After a short time the plate is removed, usually in two to three weeks. On other occasions, in similar fractures which have stopped short of becoming compound, I have used a screw running from side to side across the lower end of the tibia. (Figs. 9 and 10.)

With severe dislocation of the astragalus, and especially if it should be rotated on a vertical axis, open operation will almost certainly be required. In one of my cases there was a rotation of 90 degrees, the astragalus lying transversely across the fractured mortise. On exposure it was found that all its ligaments, save a few shreds, were torn across. The bone was replaced in position, and although it had no blood supply, and must for a period have survived by means of the synovial fluid, lymph, and blood serum surrounding it, there was a very complete recovery and a range of movement hardly limited at all.

OLD-STANDING CASES OF INCOMPLETE REDUCTION.

This is a group of cases where considerable disability has resulted from an incomplete reduction, usually a failure to correct valgus or to reduce a backward dislocation of the foot. Almost every case in this group requires operative treatment. Every one has to be considered individually, and it is impossible to generalize. I know of no cases requiring greater judgement or more resource; they are among the most difficult cases in the surgery of the extremities. The operative measures decided upon must be most thoughtfully conceived and carefully carried out in every detail, and I would not advise any surgeon who is not familiar with this class of work to experiment with it. I have illustrations of four such cases.

The first case is that of a young man of 25 years, who had a bad eversion fracture ten years before I was asked to see him.

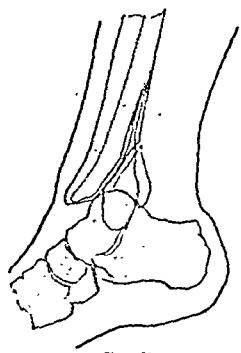

FIG. 11.

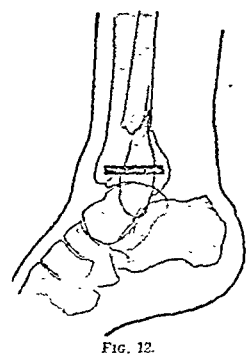

FIG. 12.

FIG. 11.—Old posterior marginal fracture, unreduced.
FIG. 12.—The same, reduced and fixed by ivory pin.

There was a much-everted foot and considerable pain. I performed a cuneiform osteotomy of the tibia and a linear of the fibula. The foot was forced over into varus. The tibia united, but a year later the fibula had not united, and was giving pain. I placed an inlay bone graft in it, and since it has united the foot has become strong, so that he has now been back at heavy labouring work for two years. His range of ankle flexion and extension is from 75 to 120 degrees.

The next case was that of a middle-aged woman who suffered from an unreduced posterior marginal fracture, which occurred two years before. Walking was impossible. The fracture was reconstructed, and the displacement reduced. An ivory pin was driven from back to front of the tibia, and the use of the ankle, whilst not normal, is greatly improved, and walking has become comfortable. (Figs. 11 and 12.)

It happens in some instances that an ankle is so painful that weight-bearing is impossible, and with or without operative treatment, reconstructive or otherwise, the patient gets no relief. I do not hesitate, in such a case, to recommend an arthrodesis of the ankle-joint. There is no doubt that a well-arthrodesed ankle is infinitely superior to one in which a moderate result has been obtained by means of a reconstruction operation.

The last case to which I wish to refer is that of a young man who had suffered in childhood from a separation of the lower end

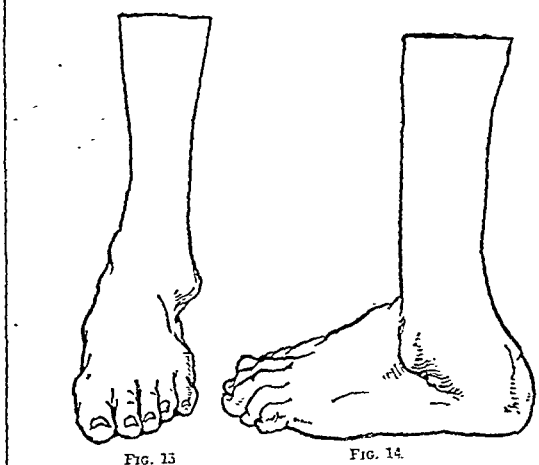

FIG. 13 FIG. 14.

Result of old separation of tibial epiphysis.

epiphysis, and in whose ankle, as growth had been interfered with, there resulted a gross deformity, which had become so bad that it was with much difficulty that he hobbled along. The appearance was as shown in the cast. (Figs. 13 and 14.) Radiograms showed a varus deformity, the fibula being curved to fit round the varus and the ankle-joint deflected more than half a right angle.

(Fig. 15.) A wedge was removed from the fibula; the tibia was divided transversely and opened out, and the gap filled up as far as possible by the piece of fibula and by shavings from the side of the tibia. Union is good, and a useful foot has been obtained. The appearance and function are now excellent. (Figs. 16 and 17.)

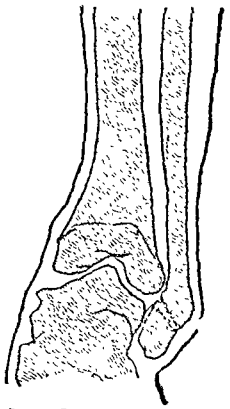

FIG. 15.—Pre-operative radiogram.

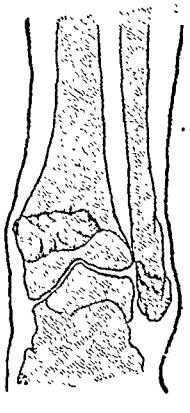

FIG. 16.—After osteotomies and graft.

FIG. 17.—Present appearance.

In conclusion, I would emphasize that function is the ultimate test of treatment, and I know of no better evidence of restoration of function than a return of the individual to his pre-accident work. I stress "pre-accident" because in some estimates of end-results a return to "work" has been accepted. The 1908 article of Clinton Dent, which has been so often quoted, stated: "I can hardly recall a case of Pott's or Dupuytren's fracture where recovery has been good enough to permit a man to return to police work. Among the Metropolitan Police 30 per cent. of all ankle injuries failed to recover for work."

This was a very serious state of affairs, and I hope that I have shown that some progress has been made since that time. Many causes have brought about this improvement, but none, I think, so much as the treatment of the fractures by one department. If you will permit me, I would like to quote the substance of two paragraphs in an article which I wrote for the *British Medical Journal* in 1921. The article was headed "The hospital treatment of fractures."[3]

In order to ensure the most perfect functional result which is possible it is desirable that the same surgeon should supervise the case from start to finish. He should be entirely responsible for the case whilst in the wards; he should supervise its manipulation and splinting, its early massage and, on discharge, its progress through the out-patient and physio-therapeutic departments. In hospitals which have no special department for orthopaedics a member, or members, of the surgical staff should be selected to take charge of the fractures. The number of beds which should be allotted to them for this purpose will, in an industrial area, be about 10 per cent. of the total surgical beds of the hospital.

This arrangement, by which the continual supervision is under one control, has been responsible more than any other single factor for the improvement which may have been obtained in our fracture results.

CONCLUSIONS.

1. Reduction of all displacements should be carried out as thoroughly and as early as possible.

2. A suitable splint which will permit constant inspection, early massage, and active movements at the earliest time should be applied.

3. Open operation in recent cases should be reserved for those in which the displacement cannot be satisfactorily reduced or maintained.

4. In old cases of mal-union operation is indicated.

5. In compiling statistics of end-results percentages should not be calculated on less than 100 cases, and "return to work" should mean the pre-accident work.

6. In the present series 89 per cent. of ankle fractures, of all types, returned to pre-accident work.

7. A fracture case, from the time of its arrival at hospital to the time of its discharge to work, should be under the supervision of one surgeon.

THE TREATMENT OF ACUTE DIVERTICULITIS.*

BY

J. P. LOCKHART-MUMMERY, F.R.C.S.ENG.,

SURGEON, ST. MARK'S HOSPITAL.

DIVERTICULITIS, like appendicitis, is, as regards our knowledge of it, a comparatively new disease, and is still considered by many doctors a very rare condition. It was not known to the last generation of surgeons, and cases of the condition were described as "pericolitis sinistra," iliac abscess, etc., and the underlying cause of such states remained unrecognizable until recently. It is now a fairly well-recognized condition, although it has hardly found its way yet into the ordinary medical textbooks of the time. Nevertheless, it is by no means an uncommon condition, and is accountable for quite a considerable number of deaths and a still larger number of chronic invalids each year.

SYMPTOMS.

The symptoms are fairly characteristic and, if recognized, are not easily mistaken for anything else. The patient is practically always over 45 years of age, and usually rather stout; for some unexplained reason the condition appears to be quite uncommon in thin persons. The main symptoms are pain in the lower part of the abdomen, tenderness in the left iliac fossa, or just above the pubes, and raised temperature, often accompanied by shivering and mild rigors. The pain is not very acute as a rule, but is distressing, and prevents the patient from moving about freely. The tenderness, if looked for, is very definite and quite characteristic of the condition. Any pressure in the lower left side of the abdomen causes the patient to flinch, and as a rule the area of acute tenderness is very well localized to a certain spot. The temperature is seldom high; usually it ranges from 100° to 101° F. rather than higher. Quite high temperatures are sometimes seen, but are exceptional, except at the onset of an acute perforation, and in this respect it differs from appendicitis, where high temperatures are the rule. Also vomiting, though occasionally a symptom, is a rare one, whereas it is a common symptom at the onset of appendicitis.

Not infrequently a definite resistance or tumour may be felt deep in the pelvis on the left side, and it may be possible to feel this bimanually, either by the rectum or vagina. It need hardly be pointed out that very gentle handling of such a tumour is advisable, or serious consequences may result. Such a swelling can, as a rule, be easily distinguished from a carcinoma of the colon by the fact that it is very definitely tender and that there are obvious symptoms of inflammation present.

The bowels may, or may not, be constipated; on the other hand, there may be a mild diarrhoea from irritation of the colon. In some cases frequency of micturition is a well-marked feature of the case, and when this is present it almost invariably means that the bladder is adherent to the diseased colon and that a perforation from the colon into that organ is threatened. Just as in the case of appendicitis, a dose of castor oil will often precipitate acute symptoms and should on no account be administered.

These symptoms apply, of course, in the main to cases of diverticulitis of the pelvic colon, by far the commonest site, and are considerably modified when the affected portion of the colon is elsewhere. The diagnosis is often extremely difficult when either the ascending or transverse colon is involved, as the symptoms then imitate several other conditions, such as appendicitis, perforated duodenal or gastric ulcer, and cholecystitis.

The acute symptoms may arise from several different causes. Most commonly one or, possibly, two diverticula have become acutely inflamed and caused a small local abscess in the bowel wall, generally just beneath the peritoneum. The inflamed area has become adherent to other structures, such as the bladder, the small intestine, the uterus, or a tube, or sometimes to the abdominal wall. Sometimes a direct perforation into the abdominal cavity is the first symptom, and in such cases a general peritonitis will occur, the exact cause of which may easily be

* Read at a meeting of the North London Medical and Chirurgical Society, February 6th, 1929

missed. Again, a sequence which is not uncommon is for a local abscess to develop around the diseased bowel and for the abscess to rupture into the peritoneal cavity. This is a disastrous happening, as it results in a very acute general infection of the peritoneal cavity owing to the large amount of septic material suddenly released into the abdomen.

The first symptom recognized may be the rupture of an inflamed diverticulum into the bladder. I have known this happen on several occasions, and the result is most distressing to the patient. An acute cystitis results, with the passage of flatus and faecal material "per urethram," and the patient is generally very ill and in great distress.

CAUSATION.

The exact cause of the formation of diverticula of the colon is not yet completely understood. There is no doubt that in some cases an inflammatory process takes place around the diverticula when they are quite small, almost microscopic, and this inflammatory process may spread to a considerable area of the bowel wall. On the other hand, diverticula may reach a considerable size and be very numerous without there being any signs at all of any inflammation around them. In fact, perforation of a diverticulum may occur and cause a general peritonitis without any inflammatory process in the bowel wall having preceded the perforation.

TREATMENT.

Unfortunately the condition is not so easily amenable to operation as is the case with appendicitis. The infective focus is not so localized, nor can it be so readily remedied by the surgeon. In the acute cases, where perforation has occurred with general peritonitis, the only treatment is to drain the abdomen and perform a colostomy well above the perforation. As a rule the perforation will be in some part of the pelvic colon, and in this event the artificial anus should be made with some portion of the left side of the transverse colon. In a few cases simple drainage of the abdominal cavity has been successful, the opening in the bowel closing up. This can hardly be relied upon, however, and is not likely to occur unless the perforation is very small. Deliberate closure of the opening caused by the ruptured diverticulum would seem a possibility, but this is seldom the case. The parts around the opening are much thickened and indurated, and such tissues do not lend themselves readily to satisfactory closure; omental grafting of the opening would be safer, but unless the diverticulitis is very localized attempts to close the opening will usually be failures and may be disastrous; colostomy is the best procedure. When a perforation has occurred into the bladder, immediate colostomy above the site of perforation is the only rational treatment. I have seen a number of such cases, and in all of them the opening into the bladder subsequently healed up quite satisfactorily.

The most difficult cases to deal with are those in which an abscess has formed in association with some part of the colon, and the abscess has subsequently burst or leaked into the peritoneal cavity. The obvious treatment is to drain the abdominal cavity and to drain the abscess cavity separately. Unfortunately what is generally found is that there is a dense mass of gut and adhesions forming the wall of the abscess, which is most difficult to drain properly, and that it is not possible to in any way disentangle or break up the adhesions without the certainty of damaging other parts of the intestine. These are most difficult cases, and even when the patient survives the initial peritonitis, residual abscesses and pocketing are the usual rule, and will call for all the skill and resources of the surgeon to circumvent. I know of few more dangerous lesions to meddle with than a mass of diverticulitis of the colon with adhesions to other organs and parts of the intestine. The lesion is highly septic and the density of tissue is only equalled by carcinoma. The abscess resembles a sponge more than an ordinary abscess cavity, and it is very difficult to establish any kind of satisfactory drainage.

When there is reason to suspect that an abscess has formed from perforation of a diverticulum, but the general peritoneal cavity is not involved, there should be no attempt to temporize in the hope that the abscess will subside. The condition is too dangerous, and even if a general peritonitis does not result, perforation of the abdominal wall or some hollow viscus will almost certainly take place and make conditions for operation more difficult. Operation in these circumstances is particularly difficult and dangerous, and very nice judgement is necessary to decide what is the best course to take. I prefer, when operating upon such cases, to use an oblique incision on the left side of the abdomen, the rectus muscle being dissected out of its sheath and displaced towards the right side; local anaesthesia of the rectus muscle is a great help. This gives very good access and allows of good draining in the flank if this should be necessary. The pelvic colon, assuming that this is the portion involved, should be freed if possible by very gentle manipulation, while the main abdominal cavity is well protected by large intra-abdominal swabs so placed as to localize as much as possible the contamination of the peritoneal cavity which may occur. The involved part of the pelvic colon should be lifted up, if it can be freed, and drawn well over into the left iliac fossa, and the abscess cavity properly drained with a tube or tubes. If the omentum is large enough it should be drawn down and stitched all round the damaged portion of the colon, so as to seal it off and at the same time prevent the small intestine from subsequently becoming adherent to it. The wrapped-up damaged portion of colon should be fixed with a few catgut sutures well into the left iliac fossa and away from the true pelvis, as if subsequent abscess formation should occur it will do less harm in this situation and will be much more accessible. I have had some very successful results from this method of treatment, and in one or two cases have been able to separate the diseased portion of the colon from the bladder, and thus prevent a perforation into that organ. Patients treated in this way have got perfectly well, and with reasonable care have been able to live normal lives for very many years. I have now quite a number of such cases under observation. They have been saved a colostomy, and the inflammatory mischief has in course of time entirely cleared up in most of them, although some have had temporary relapses. The fact that the inflammation is no longer involving the true pelvis renders treatment much safer.

If at the time of operation the damage to the bowel is too severe to justify this method of procedure a colostomy should be done well above the site of the trouble; this will generally mean a transverse colostomy. When this plan has been adopted the question will subsequently arise as to whether it is possible to close the colostomy. This is always a difficult question and will require careful consideration, as the patient's life is perfectly safe if he is content to keep the colostomy, and its closure will involve a fair amount of risk. It is doubtless worth some risk to get rid of the colostomy, but as this is mainly a question of comfort and convenience it hardly justifies running a serious risk to life.

Good *x*-ray photographs of barium enemata will be necessary to see if there is a free enough lumen to justify closing the artificial opening, and also to ascertain whether there is sufficient healthy bowel below the lesion to enable a resection to be done. If a closure is to be done it must not be postponed too long, or the bowel will have become too narrow below the colostomy. Six to eight months is probably about long enough, and, of course, in any case, complete subsidence of all inflammatory symptoms should have taken place. In most of the cases coming under my care the colon at the site of the trouble has been too badly damaged, or its lumen has become too restricted, to warrant any attempt at closing the colostomy without resection of the lesion. I have, however, on several occasions resected the damaged bowel and rejoined the ends successfully, but I have considered it safer to leave the closing of the colostomy to a subsequent operation after the newly joined bowel had properly united.

Resection of the damaged bowel is rather a difficult matter, as there are almost invariably quite a number of dense adhesions to be dealt with before it is possible to free the bowel enough for a resection, and it must always be borne in mind that we are dealing with old septic material, which must not be cut into. When the join has been

made, and as a rule only an end-to-end join is possible, the junction should be wrapped up in omentum. Occasionally it is possible to close the colostomy by short-circuiting the affected part of the bowel. In my experience this procedure has not been very successful, as the fact that faecal material can still get into the diverticulum has resulted in subsequent fresh attacks of inflammatory mischief.

TREATMENT OF GLAUCOMA BY ADRENALINE AND HISTAMINE.

(*THE SO-CALLED "GLAUCOSANS."*)

BY

W. S. DUKE-ELDER, M.A., D.Sc., PH.D., M.D., F.R.C.S.,

AND

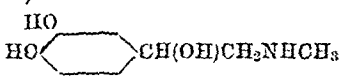
FRANK W. LAW, M.A., M.B.

(From the Royal London Ophthalmic Hospital.)

THE importance of any drug which has a beneficial effect on glaucoma, whether acute or chronic, can hardly be overestimated, and consequently it may be of interest to look into the claims made by several authors—notably by Hamburger (1923-28)—on the beneficial effect of the so-called "glaucosan" group of substances in bringing about a diminution of the intraocular tension. This name, introduced by Hamburger, is unfortunate, since the two substances upon which the "glaucosans" are based—adrenaline and histamine—are widely different in both their chemical constitution and their physiological properties.

THE ACTION OF ADRENALINE.

Adrenaline, which is the product of the activity of the chromaffine cells of the medulla of the suprarenal glands, is a methyl-amino-pyrocatechol, with the following formula (Takamine, 1901):



Since it contains an asymmetrical carbon atom there are two possible isomeric forms: the laevo-rotatory form occurs naturally, while the dextro-isomer can be made synthetically. The laevo-form is extremely active, being detectable in a dilution of one part in 250 million of saline (Pysemsky and Kravkov, 1912), but the synthetic dextro-isomer is considerably weaker, so that the racemic mixture has only about half the activity of the natural product (Stolz, 1904). Although the rationale of the action of this substance on the blood vessels has been the object of an immense amount of research since the original investigations of Oliver and Schafer in 1895, it cannot yet be said to be completely elucidated. The generally accepted interpretation of its activity at the present time is as follows:

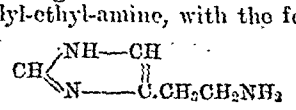
1. In very small doses it dilates the capillaries, probably by direct action upon the capillary walls, thus causing a small drop in general blood pressure (Dale and Richards, 1918) and an increase in the permeability of the capillary walls (Oinuma, 1924).

2. In larger doses, while the first action may to some extent persist, it is completely masked by an active constriction of all the arteries and arterioles which are supplied by the sympathetic nervous system; this is the generally accepted "classical" view of the action of adrenaline (see Anrep, 1912; Elliot, 1912-13; and many others), and it brings about a great increase of the blood pressure.

3. In relatively concentrated doses applied locally, adrenaline causes a direct contraction of the terminal arterioles, the capillaries, and the small venules (Cotton, Slade, and Lewis, 1915), a reaction which can be observed directly with the microscope by injecting a minute quantity into the skin (Carrier, 1922; Heimberger, 1925). Here the drug acts directly on the walls of the vessels, the reaction being equally vivid after denervation (Breslauer, 1919; Lewis, Grant, and Harris, 1927).

THE ACTION OF HISTAMINE.

There is a considerable amount of evidence that histamine, or histamine-like substances, are produced by all organs of the body. Like adrenaline it is an extremely reactive substance, an injection of one-hundred-millionth part of a milligram producing a well-marked effect. Its chemical name is imin-azolyl-ethyl-amine, with the formula:



The general action of histamine is to constrict plain muscle (Dale and Laidlaw, 1910); this includes the musculature of the arterioles, of the larger veins, and also, incidentally, of the pupil. This is accompanied by a dilatation of the capillaries (Dale and Richards, 1918), caused by a direct action on the walls of the vessels comparable to the effect of small doses of adrenaline. The first of these effects tends to produce a rise of blood pressure, and the second produces a profound fall. In such animals as the cat both of these reactions are evident; in dogs, monkeys, and man the constrictor effect on the arterioles is completely masked (Burn and Dale, 1925; Harmer and Harris, 1926), but the dilator effect on the capillaries seems to be universal throughout the mammalia (Lewis and Marvin, 1926; Lewis, 1927). So far as the blood vessels are concerned, therefore, the generally accepted action of histamine in man appears to be:

1. A dilatation of the capillaries by local direct action upon their walls.
2. A widespread dilatation of the arterioles by a local reflex nervous mechanism.
3. An increased permeability of the capillary walls leading to widespread oedema, a result of the direct action of the drug on the capillary walls (Drury and Jones, 1927).

It would seem, therefore, that in their general action the two substances, adrenaline and histamine, are antagonistic; and there is a large amount of evidence that they play such a reciprocal part throughout the body generally, histamine, or histamine-like substances, tending to dilate the capillaries, this influence being kept in check by the constrictor effect of adrenaline (and pituitrin) (see Dale, 1926).

ACTION ON THE EYE.

The action of adrenaline on the intraocular pressure was first adequately studied by Wessely (1900), Parsons (1903), and Henderson and Starling (1904), and later work has merely served to substantiate their conclusions (Thiel, 1924; Samojloff, 1925; and others). There are two main opposing influences at work: the local constriction of the vessels tends to bring about a lowering of the intraocular pressure, while the general rise of blood pressure tends to bring about a rise. In experimental animals either of these may be evident, or they both may occur, the second following the first; in man there is usually a period of hypotension which is followed by a slight rise. It would appear that in cases of simple glaucoma this reaction is retained, the fall of tension being more evident, but that in the acute or absolute forms of the disease the opposite condition may develop. When injected into the blood-stream adrenaline dilates the pupil widely, an action which is evident on subconjunctival injection, but which is retained only with difficulty on instillation into the conjunctival sac except in specially sensitive persons.

After the work of the early experimenters several clinicians used adrenaline clinically for the relief of tension in glaucoma, with, in general, indeterminate results (see summary by Rupert, 1909). Erdmann (1914) and Köllner (1918) revived its use, and recently the extensive writings of Hamburger (1923-25) have attracted considerable attention to the matter. He used the drug as a subconjunctival injection of 0.2 to 0.3 c.cm. of 1 in 1,000 solution after the instillation of holocaine, and his technique has been extensively followed (Hagen, 1923; Gradle, 1924; Römer and Krebs, 1924; Heimann, 1924; Jaensch, 1924; Kayser, 1924; Kafka, 1924; Thiel, 1924-25; Safar, 1925; Dominguez, 1925; Vannas, 1927). Fromaget (1921) employed it as a retrobulbar injection, and he has been followed by Aubaret (1923), Bailliart and Bollack (1921), Liebermann (1924), and Bonnefon (1925); Knapp (1921) relied on drops instilled into the conjunctival sac; Thiel (1925) applied it as an ointment; and Gradle (1925) on a pledget of cotton-wool. While many of these observers reported good results, they were by no means invariably successful;

their findings have been thoroughly analysed by Vannas (1927). *It has become evident that while in chronic glaucoma adrenaline may or may not do good, in acute conditions* its use is definitely dangerous. Moreover, unpleasant effects have been noted from time to time (Mans, 1924; Ring, 1925; Rentz, 1925); for a rapidly increased blood pressure with a pulse running up to 200 a minute involving a considerable amount of collapse is not a thing to be desired in the average type of person who is a glaucomatous subject.

To avoid these unpleasant consequences Hamburger (1925) turned to the less active dextro-isomer of adrenaline, and, combining it with one of the precursors in its preparation (methyl-amino-aceto-pyrocatechol), he introduced the combination as "glaucosan." He claimed that this preparation produced a local vaso-constriction without any general reaction, and that it reduced the tension of the eye, usually for several days, and sometimes for several weeks. The action was, however, so weak that a subconjunctival injection was required, and therefore, in order that the remedy could be made sufficiently powerful to be used as drops, he combined the methyl-amino-aceto-pyrocatechol with synthetic laevo-adrenaline, and produced "laevo-glaucosan." This is said to lower the tension for some days and to dilate the pupil maximally.

Hamburger (1926) considers that the primary cause of glaucoma is a "relaxation of the vaso-constricting mechanism, thereby causing a repletion of the eye with blood"; adrenaline and its derivatives lower the tension immediately by causing a vaso-constriction, and he somewhat paradoxically explains the continued hypotensive action of the drug by the supposition that the reactive hyperaemia which follows the anaemia will lead to "softening of the eye." It must be admitted that this explanation is as unconvincing as it is difficult to follow. However that may be, while good results were claimed in chronic glaucoma, the preparation appeared to be unsatisfactory in acute cases of the disease (probably on account of the mydriasis). Hamburger (1926) therefore turned to histamine (which he called "amino-glaucosan"), a substance which, as we have seen, in addition to producing a capillary dilatation, brings about a very marked miosis by its action on plain muscle. Owing to the severity of its reaction and the short duration of its effects its use in chronic cases seemed undesirable; but in acute cases which are not absolute in nature Hamburger claims good, although not invariably successful, results. The effects of these drugs in clinical cases have been recorded by Fehr (1926), Darier (1926), Koch (1927), Pletnewa (1927), Seligstein (1927), Gifford (1928), Pischel (1928), and Böhm (1928), most of whom report favourably of them, although the results have not by any means been uniformly successful, nor has their action frequently been as long as has been desired. No one, so far as we know, has reported their use in this country; and the following notes may be of interest.

CLINICAL CASES.

The two drugs employed were those recommended by Hamburger—laevo-glaucosan in cases of chronic glaucoma, and amino-glaucosan for acute glaucoma; and they were administered exactly as recommended by him.

Laevo-glaucosan (L.G.) was given after the instillation of 1 per cent. holocaine; two drops were instilled into the conjunctival sac, giving ample time for absorption, and the injections were repeated three to five times at intervals of fifteen minutes. After instillation there was a considerable reaction, and always a greater or less degree of pain. The eye became white, the pupil dilated by a varying amount, and anaemic patches were sometimes visible on the skin of the lids and the cheek. Amino-glaucosan (A.G.) was given also after holocaine, one drop of the 2, 7, or 10 per cent. solution being instilled; the great hyperaemia, sometimes with chemosis, was invariably followed by severe pain. On some occasions where it seemed to be without effect it was repeated.

A. *Chronic Primary Glaucoma.*

1. Female, aged 74; primary chronic glaucoma with symptoms of two months' standing in both eyes; was under eserine on arrival; tension *plus*. L.G. three times in one hour; marked anaemic reaction; some pain; tension unaltered. Slight dilatation of right pupil; wide dilatation of left. Eserine instilled; tension lowered (eserine now more effective). Trephine.

2. Female, aged 57; chronic primary glaucoma of right eye; twelve months. Subacute attack; pupil half dilated. A.G. instilled; repeated in one hour. Severe congestive reaction with pain. Pupil unaltered, tension slightly down. Trephine.

3. Male, aged 43; chronic primary glaucoma; one week's history of symptoms; under eserine on admission; tension high. L.G. four times in one hour; tension and pupils unaltered; reaction marked with pain.

4. Female, aged 66; chronic primary glaucoma; indefinite history. Right tension full, left tension considerably raised. L.G. right and left. Pupils fully dilated; right tension lowered, left tension practically unaltered. Trephine right and left.

5. Male, aged 47; chronic primary glaucoma of right eye; six months' history. Tension full, pupil half dilated. L.G. four times in one hour. Marked reaction with some pain; tension down to normal; pupil widely dilated. Tension remained down three days, then rose slightly. Eserine; tension fell. Trephine.

6. Male, aged 53; chronic primary glaucoma of left eye; three months' history. Had been on eserine, which had kept tension down until present subacute attack, when it was without effect. L.G. four times in one hour. Marked reaction, pupil dilated, tension lowered to normal; began to rise in three to four hours; eserine instilled hourly. Next day tension normal. Trephine.

7. Female, aged 53; chronic primary glaucoma of right eye; six months' history. Tension full, pupil dilated. L.G. four times in one hour. Marked reaction with pain; pupil and tension unaltered. Trephine.

B. *Secondary Glaucoma.*

8. Male, aged 15; iritis with raised tension of left eye. L.G. four times in one hour. Considerable irregular dilatation of the pupil, cornea brighter; tension lower after the second instillation; after the fourth pupil again small, cornea becoming hazy. Irritated by atropine; hyoscine produced dilatation to one-half in three days, when hyoscine irritation supervened and tension returned to normal.

9. Female, aged 43; iritis with raised tension: three weeks' history. Right pupil contracted. L.G. four times in one hour; pupil fully dilated, cornea clear, tension lowered. Pupil contracting in three hours; heat, etc. Uninterrupted recovery.

C. *Acute Glaucoma.*

10. Female, aged 71; acute primary glaucoma; six weeks' history of symptoms. A.G., four instillations; tension fell (90 to 60 mm. Hg (Schiötz). In six hours cornea again becoming hazy, and pupil dilating. Eserine; cornea bright, pupil small, tension small. Later trephine.

11. Female, aged 64; acute primary glaucoma; one week's history; chemosis, pupil two-thirds dilated, tension very high. Dacryocystitis with muco-purulent regurgitation. Eserine for three days; tension lowered considerably; dacryocystectomy. Eserine for one day; then, the tension keeping high, A.G. repeated in one hour. Pupil and tension as before, chemosis and pain. Twelve hours later, posterior sclerotomy; tension down. Twenty-four hours later, large central corneal ulcer developing rapidly into an hypopyon ulcer. Two days later, despite all treatment, ulcer intractable, tension raised. Eye excised.

12. Female, aged 69; acute glaucoma; two weeks' history. Tension high, pupil dilated, cornea hazy, engorged iris, small hyphaema. Eserine, leeches, heat, etc., for two days; cornea slightly brighter, tension somewhat down. A.G., violent reaction, tension and pupil unaltered. Posterior sclerotomy. Eserine continued; tension almost normal. Trephine.

13. Male, aged 73; history of haloes for four years, right and left. Pain in right eye for two weeks. Right eye: cornea oedematous, pupil one-half dilated, circular, inactive, tension stony hard. A.G. four times; pupil small, tension unaffected for some hours. Twelve hours later, no chemosis or oedema, cornea bright, pupil small, tension very much lowered, but still full. Eserine and hot bathings for four days; tension beginning to rise. Trephine (choroidal detachment followed which subsided).

14. Female, aged 58; one week's history of pain and vomiting; had been on eserine during one week before admission to hospital. Acute primary glaucoma; much injection, corneal oedema, pupil two-thirds dilated, tension high. A.G. twice with interval of one hour. No improvement after six hours, then eserine, hot bathing, leeches, etc. Next day, tension lowered but still high, cornea still oedematous. Iridectomy.

15. Male, aged 50; acute primary glaucoma; 12 hours' history; right eye. Cornea hazy, pupil dilated and inactive, tension high and much pain. A.G.; one hour later pupil small but cornea still oedematous and tension still high, although lowered. A.G. repeated; pupil unaltered, tension very much down, cornea bright. Four hours later, tension higher; eserine, hot bathings, leeches, etc. Eighteen hours later, tension still above normal, with considerable pain. Iridectomy.

CONCLUSIONS.

Fifteen cases form a small number on which to build conclusions, but from our experience of them we would suggest:

1. So far as can be seen neither of the two drugs has any prolonged effect in lowering the intraocular tension. Their action would seem to be temporary and adjuvant to other treatment, postponing, perhaps, but not without any special reason replacing, operation. The action of the drugs is neither uniform nor dramatic.

2. In chronic primary glaucoma laevo-glaucosan cann be depended upon to lower the tension; it does so in s

cases, but completely fails in others. It appears, however, that in conjunction with eserine a good effect can be produced in a case where eserine alone has remained ineffective.

3. The dilatation of the pupil caused by laevo-glaucosan may be valuable from a diagnostic point of view, since, so far as our experience goes, the dilatation is not accompanied by raised tension.

4. In secondary glaucoma laevo-glaucosan will succeed in rupturing synechiae which with other mydriatics remain unaffected. In cases of iritis with raised tension it may be effective as a preliminary measure when hesitation is felt in giving atropine at once, or where atropine has failed to relieve the condition. Owing to the accompanying anaemia, however, its repeated use would appear inadvisable in such cases.

5. Amino-glaucosan is an extremely potent miotic. It cannot be depended upon to contract the pupil and lower the tension in every case of acute glaucoma, but it would appear on occasion to be a very useful adjunct to eserine. In cases where the pupil remains dilated and the tension raised after the administration of amino-glaucosan, this preliminary treatment has undoubtedly made eserine effective subsequently in bringing about a contraction of the pupil and a lowering of the tension. No case has been met with where the drug has caused a rise of tension (as has been reported), but in several cases, although given every legitimate opportunity, it has been without any hypotensive effect.

6. Both drugs are accompanied by a severe reaction and pain, in some cases moderate, in others involving considerable distress. The occurrence of a hypopyon ulcer without other obvious cause after the use of amino-glaucosan suggests that the severity of the reaction on the superficial parts of the eye is not without danger to the cornea, especially in cases where infection is known to be present.

of the

THE PROBLEM OF PUERPERAL SEPSIS: THE BACTERIOLOGY OF THE PUERPERIUM.

BY

RICHARD R. ARMSTRONG, M.D.CANTAB., F.R.C.P.LOND.,

RESEARCH LABORATORY, ST. BARTHOLOMEW'S HOSPITAL, LONDON;

AND

HAROLD BURT-WHITE, M.D.LOND., F.R.C.S.ENG.,

ASSISTANT OBSTETRIC SURGEON, CITY OF LONDON MATERNITY HOSPITAL.

THIS paper deals with the bacterial flora of the cavity of the uterus after delivery, with special reference to the relation between streptococci and abnormalities of the puerperium. It follows our paper concerning the flora of the cervix uteri during healthy pregnancies. The importance of puerperal infection is so great that normal and morbid cases have been considered separately.

It will be seen that the widely accepted belief that morbidity in the puerperium is in the main due to a single cause—infection by *Streptococcus pyogenes*—requires modification in light of the results which follow. Particularly is this the case if the definition of puerperal pyrexia of the Ministry of Health (1926) be accepted as the standard of morbidity—namely, a pyrexia of 100.4° F. or more, affecting a woman within twenty-one days after childbirth or miscarriage, and lasting twenty-four hours on end or occurring more than once in any given twenty-four hours.

In point of fact, much confusion exists on this subject, for there is no precise definition of the several terms "morbidity," "clinical sepsis," etc., employed. This confusion is in no way dissipated by adoption of the too comprehensive standard of the Ministry, which rests on neither a clinical nor a bacteriological basis, and does not discriminate extragenital causes of raised temperature in the puerperium.

It seems very desirable to establish a method to differentiate cases of what may be termed "true" puerperal sepsis due to *S. pyogenes*, highly contagious and sometimes fatal, from morbid cases of subordinate clinical importance due to bacteria of low pathogenicity. A group of cases of "true" sepsis is described, therefore, to enhance this clinical and bacteriological contrast.

SOURCE OF DATA.

Our data are derived from examination of the following groups of cases.

(*a*) Normal puerperia exclusively. A group of 88 women confined at the City of London Maternity Hospital was examined, for the most part early in the puerperium.

(*b*) Morbid puerperia. (1) A consecutive series of 41 cases of puerperal pyrexia, as defined by the Ministry, selected from 460 women recently delivered at the City of London Maternity Hospital. (2) A series of 20 women, all of whom suffered from the severest clinical form of puerperal sepsis, some at the City of London Hospital and some at St. Bartholomew's Hospital.

METHOD.

The methods used have been those already reported in our paper on the bacteriology of pregnancy.[1] Uterine cultures have been made by a guarded swab introduced with the aid of a Fergusson's speculum. Risk of contamination of the swab from other parts of the tract was thus avoided. Aerobic and anaerobic cultures were made in every case. The investigation has been qualitative rather than quantitative. The number of organisms on a swab has often been small, for the swabs were taken for the most part early in the puerperium, from one to three days after delivery. Rather than risk overlooking the streptococcus for which we were searching, the procedure of shaking up swabs in broth, incubating, and plating out eighteen hours later, has been adopted. Use of the same technique and quantities of broth in every test has enabled us to form an approximate estimate of the richness in bacteria of every

GROUP B (1).—MORBID PUERPERIA.

STREPTOCOCCI PRESENT IN UTERUS.

Pyrexia of Genital Origin.

Case No.	Labour.	Puerperium.	Type of Streptococcus.	Other Bacteria.
9	Normal	Morbid	S. cervicis uteri	Diphtheroids
59	Normal	Morbid	S. faecalis	Enterococci diphtheroids
70	Twin birth	Morbid	S. pyogenes	B coli
73	Vaginal and perineal tears. Membranes incomplete	Morbid	S. faecalis	Haemolytic staphylococcus

*Swabbed within twenty-four hours of delivery—that is, too early. †Swabbed very late in puerperium.

sample. At the outset inoculations were made directly from swabs to plates, but often no growth was obtained on these primary plates, or at best a meagre yield, in no way representative of the flora recovered by the later method—that is, from broth cultures and plates therefrom. The bacteriological findings in each group are briefly summarized.

GROUP A.—*Normal Puerperia (88 Cases).*

The bacteria found represent the normal uterine flora during the puerperium, and are as follows.

Staphylococcus (44 per cent.).—The most characteristic and frequent organism found; appears very early and is last to disappear, not infrequently persisting beyond the lying-in period. In most instances it produces the characteristic offensive butyric odour on solid media of *S. epidermidis*. Roughly 10 per cent. of the staphylococci found caused vigorous haemolysis of the rabbit's blood medium used. The staphylococci were preferentially aerobic, favouring the view that they were of extraneous origin.

Diphtheroids (20 per cent.).—Many forms of diphtheroid bacilli were found. The majority were of robust growth, appeared early, and persisted late in the puerperium.

Döderlein's Bacillus.—Often the first organism to appear after labour, of frequent occurrence, though less often present than the staphylococcus, preferentially anaerobic.

Enterococci (19 per cent.).—Large ovoid cocci tending in broth cultures to occur in pairs or short chains of four or six, forming large luxuriant pale colonies; more probably indigenous in the vagina than derived from faecal contamination; indifferently aerobic or anaerobic.

Streptococci (19 per cent.).—*S. pyogenes* was found in 2 cases; *S. cervicis uteri* in 7 cases; *S. faecalis* in 9 cases; *S. salivarius* in 1 case. *S. pyogenes* was obtained in mixed culture from two women who experienced normal labours and puerperia. These two strains were vigorously haemolytic, and exhibited "rough" characteristics in culture; there was therefore no reason to doubt their relationship to true *S. pyogenes*, with which their biochemical reactions also agreed. The growth of members of the streptococcus group in general, and of *S. pyogenes* in particular, does not seem to us to be greatly favoured by anaerobic conditions. Anaerobiosis, however, by hindering the growth of the coarser saprophytes, assists the isolation of streptococci. Exceptionally, both growth and haemolytic power of the delicate non-pathogenic streptococcus from the cervix uteri, described in our previous paper, are assisted by anaerobiosis. This cervical streptococcus, like *S. pyogenes*, fails to reduce neutral red, and does not render raffinose and mannite broth acid, but here the resemblance ends; we suggest the name *Streptococcus cervicis uteri* for this organism.

Coliform Bacilli.—Somewhat unexpectedly, *B. coli* was found infrequently (4 per cent.). Bryce,[2] working at the Melbourne Maternity Hospital, found *B. coli* only twice in 119 cases examined in pregnancy (1.7 per cent.), and we ourselves but thrice in the series of 153 normal pregnancies reported by us (2 per cent.). The observation that this organism seldom finds its way into the genital tract under normal conditions is

more than passing interest, for, in our experience, *B. coli* is second only to *S. pyogenes* as a cause of serious puerperal sepsis, *S. faecalis* being third on the list of pathogenic by *Staphylococcus haemolyticus*.

—A Gram-negative coccus similar to that occasionally recovered from the male urethra was found in one case, but no gonococci. A paired, bean-shaped coccus, in shape and size closely resembling the gonococcus, but Gram-positive, noted also by Bryce, was found on two or three occasions. A very large coarsely growing Gram-positive coccus —the colonies described by Bryce as "crumby"—was found fairly frequently. An unnamed organism of the *B. subtilis* group grew from a batch of five swabs received on the same day, and was considered an accidental contamination. A feebly Gram-positive chromogenic bacillus, reminiscent of *B. pyocyaneus*, but forming yellow, not green, pigment, was isolated from several heavily infected swabs.

Anaerobes.—*B. welchii* was not found; other unidentified spore-bearing bacilli, not necessarily obligatory anaerobes, were occasionally found in mixed culture.

Sterile (9 per cent.).—In a few instances no growth was obtained. As will be shown later, the period of maximum floral richness in the puerperal uterus is from the third to the fifth day after delivery; the swabs of our series, therefore, were probably not all taken at the optimum time. Moreover, no normal case was examined on more than a single occasion.

GROUP B (1).—*Morbid Puerperia (41 Cases).*

Group B (1) comprises 41 cases of puerperal pyrexia as defined by the Ministry of Health standard for 1926. The group includes all the morbid cases in a consecutive series of 460 women delivered in the City of London Maternity Hospital in the latter part of last year, and may therefore be considered representative. The cases in this group are tabulated under two headings in accordance with the presence or absence of streptococci. A further subdivision is made into cases with raised temperature recognizably due to genital and those due to extragenital causes.

Generally speaking, the number of organisms present in samples from morbid cases far exceeds that from normal cases, and potentially pathogenic organisms—for example, *S. faecalis* and *B. coli*—are found more often.

The streptococci isolated were classified as *S. cervicis uteri* 4 examples, *S. salivaris* 1 example, *S. faecalis* 9 examples, and *S. pyogenes* 8 examples. *S. pyogenes* was present, therefore, in 8 only out of 34 cases of puerperal pyrexia of genital origin, to which may be added a ninth case with *S. pyogenes* abscess of the breast.

The morbid cases of this Group B (1) may also be classified from a clinical standpoint as (*a*) Minor, (*b*) Major, (*c*) Serious.

(*a*) *Minor.*—The majority, 35 cases, were mild.

(*b*) *Major.*—Three cases; *S. pyogenes* was obtained in mixed culture from the cervices of two moderately severe cases, and a third presented the clinical picture of marked and rather prolonged toxaemia, although her temperature did not exceed 102° F.; a pure culture of *S. pyogenes* was obtained from the cervix of this patient.

(*c*) *Serious.*—Three women were seriously ill; from their cervices respectively *B. coli*, *S. faecalis*, and *S. pyogenes* were recovered in pure culture. Hence the severity of symptoms in the small but important group associated with *S. pyogenes* was proportionate to the intensity of infection.

Dr. Lucy Bryce, in the paper to which reference has been made above, aptly points out that the presence in pure culture of a relatively fastidious organism such as the *S. pyogenes* probably indicates an accession of invasive power, which is associated with virulence for the host, and suggests that the organism in this condition also acquires the power of dominating in culture vigorous strains which would usually outgrow it. A precisely similar phenomenon is familiar in streptococcal follicular tonsillitis. An alternative but somewhat more abstruse explanation is based on immunological principles. It is thought that a specific infection primarily stimulates the non-specific protective mechanism, and as a result the normal and relatively harmless bacterial population is eliminated by the "first-line" defensive powers of the host. A virulent infection resists this non-specific defence and continues to thrive in pure culture until such time as it is subjected to a more slowly acquired specific immunity; at this stage the normal saprophytic population reappears.

Conversely, the occurrence of *S. pyogenes* in mixed culture is indicative of low invasive power against a resistant host, and is associated, as we have shown above, with milder clinical disturbances or none.

GROUP B (2).—*Severe Puerperal Sepsis (20 Cases).*

The onset of severe puerperal sepsis is often attended by a rigor, and the aspect of the patient is characteristic. Temperatures from 103° F. upwards, with violent fluctuations and remissions, occur, and a pulse rate of 130 and over is almost pathognomonic. In 19 out of 20 such cases chosen at random to illustrate this form of the disease a pure growth of *S. pyogenes* was obtained by swabbing the cervix; in one no streptococci were found by this method, but were present in blood culture. Including this case, blood cultures were positive in 10 cases, not undertaken in 5, and negative in 5. There was reason to believe that the number of organisms present in the blood afforded a measure of the severity of the illness. The conclusion follows that in severe puerperal sepsis *S. pyogenes* is almost universally present in pure culture in the cervix uteri and in the majority of blood cultures.

DISCUSSION OF RESULTS.

It appears to us that existing standards of puerperal pyrexia are unsatisfactory and that the definitive terms "morbidity," "clinical sepsis," "puerperal fever," etc., have no precise clinical or bacteriological basis. As a practical alternative we suggest the comparatively simple procedure of examination of a swab from the uterus in all doubtful morbid cases, believing that the cervical swab is of the same value in the diagnosis of streptococcal puerperal sepsis as is the throat swab in diphtheria. Actually, the recognition of the vigorously haemolytic *S. pyogenes* on blood agar plates is an even simpler matter than the identification of the Klebs-Loeffler bacillus from serum. Cases proven due to *S. pyogenes* infection would call for guarded prognosis, and steps would be taken to prevent spread of infection; in the remainder, treatment would proceed along general lines without need for isolation or notification.

As the matter stands at present, if the "severe" and "clinically septic" cases be excluded from consideration, it appears that there is no essential difference between the bacterial flora of the normal and of the morbid puerperium. The injuries and exhaustion which follow prolonged labour, with or without instrumental delivery, seem the decisive factors in rendering the maternal tissues vulnerable to infection by otherwise harmless bacteria. Cases of this class relatively seldom give serious anxiety to the obstetrician and are not infectious.

The picture presented by cases of *S. pyogenes* infection is altogether different, and it is this which has at all times excited the attention of observers, both on account of the severity of the illness and the rapidity with which infection spreads from case to case. As a consequence, bacteriological investigation of the lesser degrees of morbidity have not been sufficiently undertaken, while the preponderance of *S. pyogenes* infection in the more serious cases has led to the admittedly erroneous conclusion that puerperal morbidity is in the main due to this organism.

A similar conclusion has been reached by Colebrook,[2] who, however, in a letter to the *British Medical Journal*, reports *S. pyogenes* as a sporadic infection in only 6 out of 85 morbid cases recently examined by him at Queen Charlotte's Hospital. We do not fully understand the finding of so few examples of *S. pyogenes* in Colebrook's series, but we are whole-heartedly in accord with him in advocating routine bacteriological examination of the cervix uteri in morbid cases.

THE COURSE OF BACTERIAL INVASION OF THE UTERUS DURING THE PUERPERIUM.

The manner in which the normal condition of bacterial sterility within the uterus is restored is not without practical importance as bearing on the question of treatment by douching, etc., during the puerperium. In the course of studying our first group of 88 cases it became apparent that the uterus was invaded very soon after delivery by a profuse growth of organisms from contiguous surfaces which diminished in the later days of the puerperium.

FitzGibbon and Bigger[4] found streptococci in the uterus in 27 of 50 women examined, and later, using even greater care to obtain samples exclusively from the cavity of the uterus, found streptococci in 7 of 25 women examined on the fifth to the sixth day after delivery. Their attention was concentrated on the streptococcus group, and no account was taken of other organisms present.

Stühler and Winckler[5] found the uterus free from infection in most cases by the ninth or tenth day, and, in a

later research, using improved methods, obtained no more than 30 per cent. of positive cultures by that time.

Loeser[6] investigated the problem still more thoroughly, finding the uterus sterile immediately after delivery, but gradually becoming infected so that 25 per cent. of all cervical cultures were positive on the first day, 50 per cent. on the second day, and 100 per cent. on the third day of the puerperium, infection of the fundus uteri following later, reaching its height by the fifth day and afterwards diminishing.

This was confirmed by the study we conducted at frequent intervals during ten days of a trial group of 12 cases. We found the uterus to be invaded almost at once, [illegible]s being obtained in some cases within five to si[illegible]rv; infection increased until the third day, [illegible]ed or diminished slightly by the fifth day, a[illegible]t disappeared by the eighth day. This progres[illegible]n, culminating at the third to the fifth day, a[illegible]ready explanation of the observed delay in the [illegible]oment of puerperal pyrexia until this time. In one-third of a series of 74 febrile cases analysed by us,[7] a rise of temperature occurred on the third day, and in two-thirds from the second to the fourth day inclusive.

Everard Williams and Reynolds[8] have shown that barium sulphate emulsion, dropped into the uterine cavity by means of a specially designed cannula and syringe, gradually passed into the Fallopian tubes and reached the peritoneal cavity through the abdominal ostia. The process was traced by consecutive radiographs. They found by experimental ligation of the tubes that barium salts insufflated into the vagina in rabbits travelled upwards only when the ostia were open. The motive force was held to be an aspiration into the abdominal cavity, and ascending infection of the genital tract was thus explained. It appears, therefore, that the uterus after delivery is inevitably invaded by bacteria from contiguous sources, irrespective of manipulation.

Conclusions.

1. The organisms recovered from the uterus after labour in the majority of cases of "puerperal pyrexia" are similar to those which are found in normal puerperia. It seems possible that the injuries incidental to prolonged labour or instrumental delivery are the chief factors which determine the minor pathogenicity of which these organisms appear to be capable on occasion.

2. *Streptococcus pyogenes* is occasionally found in the absence of symptoms of disease, but in that case it is always in association with other organisms.

3. When *S. pyogenes* is found in cases of "puerperal pyrexia" the severity of the illness is proportionate to the number of streptococci present. The presence of *S. pyogenes* in the cervix uteri should remove the case from the category of "puerperal pyrexia" and allot it to that of "puerperal fever," to be treated accordingly.

4. A means of differentiating *S. pyogenes* infection from [illegible]auses of morbidity is required in cases of doubt [illegible]very case occurring during an outbreak of puer[illegible]is. Bacteriological examination of the cervix [illegible]effective method of diagnosis.

[illegible]e uterus is rapidly invaded by bacteria from con[illegible]ous surfaces early in the puerperium.

6. Uterine infection normally increases up to the third or fifth day and afterwards diminishes.

We are indebted to Mr. Malcolm Donaldson for valuable criticism and advice, and acknowledgement is due from one of us to the Medical Research Council for assistance in conducting the experimental inquiry. We thank the members of the staffs of St. Bartholomew's and the City of London Maternity Hospitals for access to their cases.

PURPURA FULMINANS FOLLOWING A MILD CASE OF SCARLET FEVER.

BY

THOMAS A. PRATT, M.B., Ch.B., AND HUGH W. O. FREW, M.B., Ch.B., D.P.H.,

ASSISTANT PHYSICIANS, CITY OF GLASGOW HOSPITAL, KNIGHTSWOOD.

THE following case of purpura fulminans occurring in the course of scarlet fever is, on account of its rarity, worthy of record.

The patient, a girl of 5 years, was admitted to hospital as a case of scarlet fever. The history was to the effect that three days previously she had an attack of sickness, headache, and sore throat, followed by the appearance of a rash on the trunk and limbs. On examination she appeared thin and under-developed. The cheeks were flushed, and she had definite circumoral pallor. A bright punctate rash was present on the body and limbs. The tongue was coated, though peeling had commenced at the margin, and the papillae were enlarged. The throat was congested and [illegible]e the tonsils were enlarged. There was a slight degree of cervica[illegible] of adenitis. Examination revealed no abnormality of the heart a[illegible]tract the lungs. The temperature was 100° F., pulse 124, respirations 28.

During the succeeding days the child appeared to be quite comfortable. She took her food well and slept well. The pyrexia which was present on admission continued between 99° F. and 100° F. for three days, when it rose to 102° F. This rise coincided with an increase in the size of the cervical glands. On the sixth day the temperature fell to normal and remained so throughout. The cervical adenitis subsided completely in a few days. Apart from this rise of temperature there was absolutely no indication of the approach of the more serious condition.

On the morning of the twenty-first day of illness an alteration was noted in the general appearance of the patient. She was now dull and listless and very pale. The pulse, though not increased in rate, was softer than it had been previously. Examination showed areas of ecchymosis over (1) both trochanteric regions, (2) the lateral surfaces of the thighs, (3) the posterior surfaces of the calves. These areas were of a deep purple colour with a narrow bluish margin, and the outline presented a definite scalloped appearance. On palpation there was no tenderness and the affected parts were rough and indurated. On the posterior surface of the left calf the condition had advanced further and a large vesicle had formed on the area of ecchymosis. When seen later in the day the child had become much worse. The pulse rate was increased and the breathing was rapid and shallow. The areas of ecchymosis, especially those on the upper part of the legs, had increased greatly in size. During the night the condition progressed rapidly and the child died the next morning.

Post-mortem Findings.

At the *post-mortem* examination the following points were noted. The areas of ecchymosis extended over part of the anterior, the lateral, and the posterior surfaces of both thighs, and reached from the level of the great trochanter to within two inches of the knee-joints and spread over the posterior and inner surfaces of both calves. There was also an area on the sacral region. An incision was made across one of the areas so as to involve both affected and unaffected parts, and it was found that the affected tissue was deeply injected. The demarcation of affected from unaffected tissue was as well defined in the deeper tissues as on the surface. On examination of the various organs there was no evidence of any internal haemorrhage. The heart, lungs, liver, spleen, kidneys, and bladder all appeared quite normal. In the stomach and intestine there was not the slightest evidence of petechial haemorrhages.

Discussion.

The remarkable feature of the case was that the rapidly fatal condition followed on a very mild attack of scarlet fever. Further, there was an entire absence of any haemorrhage such as bleeding from the gums or from any other mucous surface, haematemesis, melaena, or haematuria.

Other points of interest were the occurrence of the condition at the end of the third week, the sudden onset with no premonitory symptoms, and the very short duration of the purpuric condition. The ecchymosis was confined to the lower limbs and was more or less symmetrical.

A few somewhat similar cases have been recorded. Kerr[1] reported a few cases of purpura haemorrhagica, all of

which, however, were associated with haematemesis and haematuria, and followed cases of septic scarlet fever. Goodall and Washbourn[2] have recorded four cases of fulminating purpura haemorrhagica, and they regarded the condition as a rare complication of scarlet fever. The cases of Rolleston and McCririck[3] were characterized by the absence of haemorrhage from mucous membranes, and in this respect they resembled the one under discussion. However, the period of illness from the first appearance of ecchymosis till the fatal termination was in the present case extremely short. The total duration was only thirty hours. These features bring the present case into the category of purpura fulminans.

A CASE OF ELEPHANTIASIS NEUROMATOSA.

BY

R. L. SPITTEL, F.R.C.S.,
SURGEON, GENERAL HOSPITAL, COLOMBO;
AND
S. E. FERNANDO, L.M.S.,
CEYLON.

VON RECKLINGHAUSEN in 1882 drew attention to an association of lesions affecting the skin and nervous system—namely, soft tumours of molluscum fibrosum, cutaneous pigmentation (freckles and maculae) scattered all over the body, and multiple fibrous tumours of nerves. Since then two other manifestations, occasionally present, were found to be classifiable in the same group—namely, plexiform neuro-fibroma and elephantiasis neuromatosa of Virchow.

Diffuse neuro-fibromatosis, or von Recklinghausen's disease, consists essentially of a diffuse overgrowth of the connective tissue of the nerves, especially that of the endoneurium separating out the nerve fibres. The fibrous overgrowth may be confined to a single nerve or a plexus, or it may be generalized to include cranial, spinal, and sympathetic nerves—large or small, superficial or deep. When the small nerves in the skin and subcutaneous tissues are affected the overgrowth spreads beyond the nerve filament in which it originates, causing soft fibrous tumours of the skin (molluscum fibrosum), which may be few and widely spread, or so abundant as to cover every inch of an individual except his palms and soles. They vary from the size of a pin's head to a fig, and may be sessile or pedunculated.

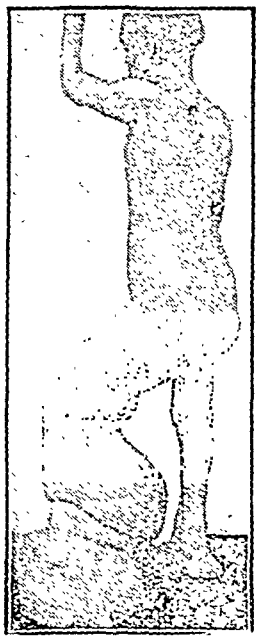

FIG. 1.—The patient. Note the pendulous scalp in the occipital region and subcutaneous nodules in the affected limb.

Plexiform neuro-fibroma is a fibromatosis affecting a group of contiguous nerves, commonly those of the head and neck (fifth and superficial cervical). Commencing shortly after birth, it gradually forms a pendulous mass composed of convoluted, thickened, or beaded nerve cords held together by connective tissue.

Elephantiasis neuromatosa of Virchow is closely allied to plexiform neuro-fibroma and molluscum fibrosum. Here the fibromatosis of the cutaneous nerves merges into a diffuse overgrowth of the skin and subcutaneous tissue, uniformly enlarging the affected region, such as a limb, as in other forms of elephantiasis. The overlying skin may be normal, thickened, or pigmented, and may sometimes contain palpably thickened and coiled nerves, as in plexiform neuroma. The condition is usually congenital and starts at a pigmented spot or a molluscum fibrosum.

In many cases of neuro-fibromatosis death results from sarcoma, the change manifesting itself clinically by rapid enlargement of the lesions. The only treatment is excision of removable masses.

The case here reported is remarkable for the colossal growth of a limb.

The patient, a male Tamil, looks more like a boy of 15 than the man of 20 he is said to be. His outstanding feature is the gigantic size of the left lower limb, which forms a pendulous mass representing about a third of his body weight, and prevents

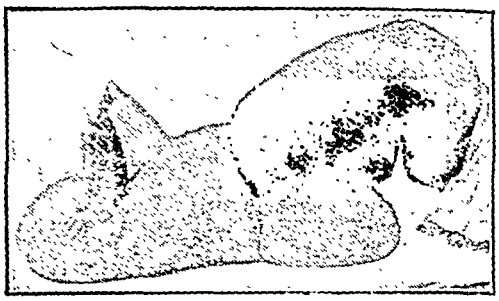

FIG. 2.—The affected portion of the limb before amputation.

him from walking except with the very greatest difficulty. The abnormality is said to have been present at birth and to have progressed with the growth of the boy, especially during the last fifteen years. In addition, he presents the following lesions: small, soft, freely movable, painless, subcutaneous tumours scattered all over the body, particularly on the abdomen, but absent in the palms and soles; a small pachydermatocele of the occipital scalp; pigmentation of the skin in the form of freckles and larger maculae—the palms are pigmented, the soles less so; pigmentation of the mucous membrane of the mouth; and muddy discoloration of the conjunctivae as in argyrosis. He complains of some pain in the affected limb. His mental faculties are not impaired.

Skiagraphy showed a marked atrophy of the epiphyses and smaller bones resulting in distorted outlines. The shafts of the long bones showed an irregularly distributed thickening of the cortex, and greater elongation than on the sound side.

Treatment consisted of amputation at the upper third of the thigh, under spinal anaesthesia. Considering the amount of tissue removed the patient stood the operation very well. The amputated limb weighed 35 lb., the rest of the patient 65 lb.

Dissection of the Amputated Limb.—Apart from the enormous increase in the connective tissue of the soft parts there was also an increase in the bony development, as evidenced by the greater length of the affected limb. The normal tibia (right) was 12 inches long, the abnormal one 15½ inches. The normal fibula was 12 inches, the abnormal one 16½ inches, its lower end curving round the astragalus like a smoker's pipe bowl, and thrusting up the foot bones into a position of talipes equinus (Fig. 3). The skeleton of the affected foot was only a quarter of an inch longer than the other. Both tibia and fibula were bowed, rough, and pitted, the latter especially about its middle. The periarterial sympathetics of the femoral artery at the site of amputation were visibly enlarged. Professor A. G. Smith, to whom I sent a section of it, reported as follows:

FIG. 3.—Skeleton of amputated limb.

"The lumen of the artery seemed to be small. It, and to a lesser extent the vein, were completely ensheathed in a mass of flattened, hypertrophied, tortuous nerve cords—evidently greatly enlarged periarterial sympathetics. The individual nerve bundles were clearly to be distinguished."

Histological examination by Professor Ellison confirmed that the hypertrophied nerves belonged to the autonomic system. He said they were the finest example of non-medullated nerve tissue he had ever seen.

It is interesting to consider what part the autonomic hypertrophy played in the overgrowth of the limb. Were they parts of the same process, or were the hypertrophied sympathetic nerves responsible, even partially, for the generalized overgrowth of the limb, through disordered vaso-constrictor and secretory impulses?

FIG. 4. Patient's mother.

The patient's mother (Fig. 4), who was about 40 years of age, was 5 feet in height, and her physique suggested achondroplasia. The patient was her only child. Despite a certain degree of deformity of her infant's limb at birth, there was no special trouble at the confinement. She said that her parents were normal, but that her grandmother showed similar lesions to hers, which consisted of over 2,000 minute cutaneous tumours and scattered subcutaneous swellings; freckles and patchy pigmentation of the skin; and a diffuse swelling on the dorsum of the right leg, which was stated to be similar to the initial lesion affecting her son.

EOSINOPHILIA IN INSULIN THERAPY.

A PRELIMINARY REPORT TO THE MEDICAL RESEARCH COUNCIL.

BY

R. D. LAWRENCE, M.D., AND O. B. BUCKLEY, M.B., M.R.C.P. M.R.C.P.

THE occurrence of a high degree of eosinophilia in a diabetic patient treated with large doses of insulin was first observed in 1927.[1] Various blood counts gave percentages of 12, 20, 11, 15, and 17.5, and a thorough investigation showed none of the usual causes of eosinophilia to be present. It therefore seemed possible that insulin therapy *per se* might be responsible for the abnormal blood count, and this point has been investigated in other diabetics. It has been found that, of the 20 insulin cases examined, 10 show an eosinophilia varying between 4 and 20 per cent.

Non-Insulin Diabetics.

As far as we are aware, no abnormal eosinophilia has been reported in diabetics. To control this point blood counts have been carried out on 12 diabetics who were not having insulin. In only one (and he suffers intermittently from eczema) has an eosinophilia of over 4 per cent. been found. The others are mostly between 0.5 and 2 per cent., the same as in the non-diabetic population attending our out-patient departments. An eosinophilia of 4 per cent. or over has therefore been taken as a definite degree in classifying our results.

Insulin Cases.

Twenty insulin cases, of all ages and degrees of severity, have been investigated. Of these, 10 have an eosinophilia of 4 per cent. or over, and 5 of 9 per cent. or over. The highest observed is 20 per cent. In none has there been any evidence of parasitic or skin diseases, and the only asthmatic had a low count of 1.6 per cent. No factors have been observed to account for the production of eosinophilia in half these cases and its absence in the other half, such as general allergic tendencies, varying skin reactions at the site of insulin injections, or variations in the diet followed. On the whole the eosinophilia bore no relation to the size of insulin dose, although one insulin-resistant case on 200 units a day showed the highest figure. In a few cases, where repeated blood counts were carried out, considerable fluctuations in the degree of eosinophilia were observed. One case showed 17 per cent. at one time and only 0.8 per cent. on another occasion four months later. It is possible, therefore, that eosinophilia may have been temporarily present in others of our series, but was not discovered by a single blood count. It was noticeable that an increase in the eosinophilia occurred in several cases during the very hot weather in July and August, 1928, being lower before and after these months. This observation we intend to confirm next summer if climate permits. It would be interesting to know the degree of eosinophilia in insulin cases in hot countries.

The Cause of the Eosinophilia.

So far we have only established the presence of eosinophilia in a large proportion of insulin-treated diabetics and its absence in non-insulin cases. No factor other than the insulin has been discovered to account for this eosinophilia. The following ways in which insulin may be responsible suggest themselves.

1. Insulin, by virtue of its physiological action, might produce an eosinophilia. This is hardly likely, and the fact that we have found an eosinophilia in a case of diabetes insipidus treated by injections of pituitary extract is against this possibility.

2. The eosinophilia may be an allergic phenomenon produced in susceptible patients by the protein nature of insulin or by protein impurities in the solution. The latter, however, are almost absent in the brands of insulin (B.D.H. and B.W.) used by most of our patients. Moreover, there has been no sign of local allergic phenomena, such as wheals and urticaria, in these cases.

3. Insulin, being an acid solution, has an irritative effect on the skin and subcutaneous tissues, manifested locally by stinging and oedema at the site of injection. Eosinophilia is possibly produced by this constant skin irritation in the same way that it is so frequently associated with skin disease.

No definite explanation of insulin eosinophilia can be offered at present. The possibilities are being further investigated.

SUMMARY.

An eosinophilia has been found in 10 out of 20 diabetics treated with insulin. It is absent in cases treated without insulin.

INSULIN FAT ATROPHY A TRAUMATIC ATROPHIC PANNICULITIS.

BY

HAROLD AVERY, M.B., B.S.LOND., M.R.C.P.,

MEDICAL REGISTRAR, CHARING CROSS HOSPITAL, LONDON.

A PECULIAR form of local fat atrophy in the subcutaneous tissues following repeated insulin injections has been described, and a case was shown by me before the Clinical Section of the Royal Society of Medicine.[1] In all cases, despite instructions to the contrary, the insulin has been repeatedly injected into the one area instead of varying the site. The situation of the atrophy varies with the site of injection, the arms, thighs, and abdominal wall having been affected. A dimpling of the skin first appears, the depression then spreading in area and extending deeply. As a rule the underlying tissues are not affected, but where the injections have been given deeply the underlying muscle may also atrophy; the skin may adhere to the underlying tissues, but does not itself undergo any change in texture. Neurological changes are generally absent,[2 3] the integrity of the somatic and sympathetic nerve supply being demonstrated by the presence of all forms of sensation, and the pilomotor (goose-skin) reflex on faradic and direct galvanic stimulation[4]; impairment of pain, tactile and thermal sensation may, however, occur.[5] In one of the cases reported no sign of the atrophy remained two and a half years after ceasing injections, though the depression had been deep and distinctly felt through the clothing.[6] The

following brief account of my patient's history is fairly typical.

A married woman, aged 56, a Dutch Jewess, large and rather obese, has suffered from diabetes mellitus for fifteen years. There is a strong family history of the complaint, two sisters and two maternal uncles suffering from diabetes, and her mother having *died in diabetic coma*. The urine has been intermittently sugar-free, but the patient will not keep to a strict diet. Thirst, polyuria, and pruritus vulvae have not been present for some years. There are now no abnormal symptoms except a feeling of lassitude and ill health when the diet has been too generous; physically she appears quite healthy.

Insulin therapy was begun in March, 1927, 20 units twice daily being injected into the arms, more or less in the same area each time, some of the injections being given deeply. In March, 1928, the patient noticed a dimpling of the arms in the injection area, which began to extend deeply. Synthalin treatment was attempted, but was useless in controlling the glycosuria, and insulin therapy was therefore continued by injections into the thighs.

Physical Examination.—The patient has well-covered arms, but on each side of the point of injection below the insertion of the deltoid there is a deep depressed area where subcutaneous fat seems to have entirely disappeared. The skin here appears perfectly normal and is not adherent to the underlying muscle; there are *no sensory nervous disturbances, objective or subjective*, and the pilomotor reflex is intact. The muscle at the bottom of the depression feels abnormally thin, and the humerus can easily be felt through it. Power and function in the arm are not impaired; indeed, the condition gave rise to no symptoms until the patient's fear was aroused by the indiscreet remarks of a medical attendant who prophesied paralysis, so that she now complains of a feeling of weakness. The thighs show an early stage of the same lesion. The fasting blood sugar (November 8th, 1928) was 0.142 per cent., and urine sugar 1.84 per cent.

The accompanying table is an analysis of the recorded cases of this condition. Case 1 is my own; Cases 2 and 3 were described by Barborka[7]; Cases 4, 5, and 6 by Carmichael and Graham[3]; Case 7 by Chapman[6]; Cases 8 to 12 by Depisch[5]; Case 13 by Mentzer and du Bray,[2] and Cases 14 to 21 by Rabinowitch.[8]

Case.	Sex.	Age.	Duration of Diabetes in Years.	Duration of Insulin Treatment.	Case.	Sex.	Age.	Duration of Diabetes in Years	Duration of Insulin Treatment.
1	F.	56	15	1	12	M.	38	7	2
2	F.	34	4	½	13	F.	54	6	2½
3	F.	60	½	½	14	M.	38	5	3½
4	F.	49	5	1½	15	M.	22	2	2½
5	F.	39	18	3	6	F.	14	2½	2½
6	M.	8	—	2	17	M.	8	½	1½
7	F.	48	—	½	18	M.	42	1½	1½
8	F.	50	—	½	19	M.	54	4½	3½
9	F.	45	5	½	20	F.	35	2½	2½
10	F.	54	4	1	21	F.	28	3½	3½
11	F.	53	—	½					

Fourteen of the 21 recorded cases have occurred in women, a fact which, taken together with the greater incidence of diabetes in men, suggests that women are definitely more liable than men to suffer from the condition. The age incidence varied between 8 and 60 years, with an average, including two boys aged 8 and a girl aged 14, of 39.5; excluding these children the figure is 44.4 years. The known duration of the diabetes has varied from 6 months to 18 years, with an average of 5.3 years, whilst the duration of insulin therapy before the appearance of the fat atrophy has varied between 3 months and 3 years 6 months, with an average of 1 year 8 months. The dose of insulin has varied from 10 to 120 units daily, being given in one, two, or three injections a day. The *duration of treatment before the onset of atrophy appears* to bear no relationship to either the dose or the daily number of injections of insulin. The amount of subcutaneous fat is of no significance as some of the patients have been obese and others slender.

In Case 2 there was no further atrophy three months after ceasing injections; in Case 6 improvement began in three weeks, and in Case 7 no sign of the atrophy was present two and a half years afterwards. Cases 6, 14, and 18 were complicated by pulmonary tuberculosis; Cases 3 and 19 had advanced arterio-sclerosis.

In the early days of insulin therapy acute local reactions such as necrosis and sterile abscesses occurred, but with the introduction of better preparations they became rare. An urticarial type of reaction, either local or general, and probably due to protein sensitiveness, is occasionally seen, especially among patients using the American iletin (insulin Lilly), which is prepared from pig pancreas; with the elimination of extraneous substances, and improvement in the technique of preparation, even these reactions are becoming rare. It is unlikely, however, that foreign proteins are the cause of the local fat atrophy described, as in only one of the cases recorded was there any undue immediate reaction[3]; with this patient there was at first a local reaction with English insulin, but on returning to this preparation after using Lilly insulin no reaction was obtained.

Examination of rabbits shortly after an injection of insulin[9] elicits no signs of degenerative changes in the connective tissue cells of the panniculus adiposus, but these *cells are widely separated by a mucigenous fluid, which* produces the localized subcutaneous oedema seen following an injection, and which in the human subject takes eighteen to thirty-six hours to subside. The neighbouring muscles, however, show marked degenerative changes, with leucocytic infiltration, as appears to happen in human muscle if the insulin is deeply injected. Lawrence[10] found that after frequent injections of insulin sections of the skin showed infiltration in the neighbourhood of the vessels by lymphocytes and histiocytes, with some plasma cells and eosinophils, whilst three years after discontinuing the injections there were, in addition, fibrous strands passing down from the corium and dividing the fat into coarse lobules. Mentzer and du Bray, on the other hand, were unable to find lymphocytes in their patient, but recorded *the presence of a calcified cyst.*

It is perhaps natural to attribute the disappearance of the fat to the presence in the insulin of fat-splitting enzymes derived from the pancreas, but Rabinowitch,[8] after concentrating down large quantities of insulin (under low pressure and temperature), was unable to detect pancreatic lipase on applying the usual tests—litmus milk, copper soap, olive oil bile, and ethyl butyrate. He therefore concluded that, unless his method of concentration destroys lipase, none is present. The sterilization of the needle is not at fault, as is shown by the diversity of methods employed by the patients (boiling, ethyl alcohol, lysol, and methylated spirit); the brand of insulin used has also varied among the cases (Lilly, Burroughs Wellcome and Co., Chemosan).

That the reaction in the subcutaneous fat is not specific is borne out by the fact that the early histological appearances following injections of insulin, hypertonic glucose, or saline solutions are identical[9]; whilst the depressed areas of fat atrophy have been observed at the injection sites in narcotic addicts,[2] and foci of lymphocytes have been found on section. A somewhat similar condition, but far more intense and advanced, is seen in traumatic fat necrosis of the breast, where areas of necrosis and liquefaction in the fat are surrounded by abundant newly formed connective tissue.[11 12]

It is probable that the injection of insulin or other substances damages the delicate protoplasmic cell envelope of the fat cells so that fat globules are released, and, acting as foreign bodies in the tissue, result in the formation of histiocytes which take on lipophagic activity. When the slight trauma is constantly repeated, atrophy of the fatty layer is likely to result. If the trauma is more severe, as following an injection of ether into the subcutaneous tissues, a similar but more intense reaction may result,[13] with the formation of a greater amount of fibrous tissue, so that a close resemblance to the appearance in traumatic fat necrosis of the breast is seen.

A patchy atrophy of the fatty layer of the skin resembling the condition under discussion, preceded by the ingestion of the fat by large phagocytic cells, has occurred in association with periods of pyrexia, suggesting an infective origin of the lesion[14]; whilst similar histological appearances were described by Parkes Weber in a case of relapsing panniculitis.[15]

Conclusions.

The subcutaneous fat atrophy described as following repeated injection of insulin into the subcutaneous tissues is a non-specific reaction, the result of repeated small traumata to the panniculus adiposus, and not due to the presence of any pancreatic lipase in insulin, so that the condition might suitably be called a traumatic atrophic panniculitis.

I wish to express my thanks to Dr. du Bray of San Francisco, Dr. Chapman of Bridlington, Yorks, and Dr. Rabinowitch of Montreal for supplying me with details of their cases.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PAINLESS LABOUR WITH INVERSION OF THE UTERUS.

IN view of recent communications on painless labour I believe that the following clinical notes may be of interest.

A multipara, aged 27, had had two previous pregnancies, both of which were normal. She was breast-feeding the last baby when she became pregnant and, therefore, had no idea of the date of commencement of pregnancy.

On November 15th, 1928, she had been performing her daily household duties as usual. At 4.20 p.m. she complained of "slight stomach-ache" with a desire to defaecate: at 4.30 p.m. she had a slight motion, and as a result of straining "felt something come down into her front passage." She arose from the lavatory seat, and without any pain, so she states, delivered herself of a child, which fell to the floor, the umbilical cord being torn. She picked up the infant, went upstairs, and lay on her bed. A friend notified the maternity department of the Radcliffe Infirmary, and a nurse was sent out; she found the patient in good condition with a pulse of 96 per minute, and the child rolled in a blanket. She ligatured the umbilical cord, which was about 3 inches long. The placenta was lying in a pool of blood on the floor. The nurse then examined the mother, and found at the vulva a swelling which she rightly diagnosed as an inverted uterus. She wrapped the organ round with sterile pads and sent for the patient's doctor, who at once ordered the patient to the maternity department of the hospital.

When I saw the patient the pulse was good and she was not in the least degree in a state of shock; I found a partial inversion of the uterus with a portion of the membrane still attached. She was given an anaesthetic, and the surrounding areas and vulvar hair were thoroughly treated with iodine, the inverted portion of the uterus being cleaned up with mercury biniodide (1 in 1,000). I stripped away the membranes and returned the uterus to the pelvis, and the patient was then given a hot intrauterine douche of mercury biniodide (1 in 4,000) followed by saline solution. I injected intramuscularly 1 c.cm. of pituitrin with the same amount of aseptic ergot.

The patient did not have the slightest rise of temperature throughout the puerperium; she and her child left the hospital on the twelfth day, perfectly well. She gave the history that with her first labour she had definite labour pains throughout, but not excessive. With her second confinement "had only about two pains, and these were quite trivial." The present labour was quite painless.

The interesting points of this case are the entire absence of shock, which one usually associates with inverted uterus in the course of delivery; the puerperium absolutely normal; and the child none the worse for its unusual entrance into the world.

I am indebted to Dr. F. G. Proudfoot, K.H.S., the senior honorary obstetric physician, for permission to publish this case.

HENRY R. SPARROW, M.B., B.Ch.,
Obstetric House-Physician, Radcliffe Infirmary, Oxford.

LOCAL INJURY AS A POSSIBLE CAUSATIVE FACTOR IN SARCOMA.

REPORT OF A CASE.

INJURY has been regarded as an exciting cause of malignant tumours from the earliest times, and especially by the laity. The part played by various forms of chronic irritation in the production of certain types of epithelioma is undeniable. Dealing with bone sarcoma, Coley (*Annals of Surgery*, April and May, 1911), in a review of 270 cases, traced a history of antecedent local injury in 23 per cent. Of these, in 38 per cent. the tumour developed within the first month after the injury, and in 70 per cent. within the first six months. Discount must be made for the numerous slight traumata to which every active individual is constantly subject, and which may be recalled only by close questioning after the development of a tumour. But the following case illustrates so closely the rapid growth of a sarcoma in direct relation to a definite injury that it seems worthy of record, although it is not possible to be certain that the injury did not merely break down and disseminate a small pre-existing focus of malignant disease.

A railway signalman, aged 45, was in perfect health until April 19th, 1928. On that day, while on duty, he was pulling over a heavy signal lever with his left hand and his head was turned fully to the right, as he was speaking to the telephone boy. He felt something snap in the left side of his neck, and at once experienced a sharp pain, severe enough to make him sit down. He consulted his doctor on April 21st. Dr. Harrowell of Great Haywood found on that day a small swelling the size of a hazel nut under the middle of the left sterno-mastoid muscle. The man continued at work until May 4th, when he again saw his doctor, as the swelling was increasing in size. He ceased work on that day. A skiagram taken a few days later showed no evidence of injury to the cervical vertebrae.

On May 13th his condition was as follows: A florid healthy-looking man, cheerful and in no discomfort. The left side of the neck, from the mandible to below the clavicle, was the seat of a brawny swelling, more prominent in the middle, extending forwards to the margin of the larynx, and back to the edge of the trapezius muscle. The swelling was not tender, it did not pulsate, and no thrill was felt or heard over it. The skin at its margins showed a bluish-purple discoloration. The left pupil was contracted and there was definite weakness in the left deltoid muscle. He was afebrile.

He was admitted to hospital on May 19th. The swelling had markedly increased in size in the interval. On May 21st the left arm became oedematous and paretic. Two days later he could only swallow fluids, and his voice was reduced to a whisper. On May 24th an exploratory operation was undertaken in the hope of relieving the laryngeal pressure. The whole left side of the neck was infiltrated with growth; he died some twelve hours later of cardio-respiratory failure.

Post-Mortem Examination.—Body well nourished, left arm oedematous. The swelling of the left side of the neck extended from the mastoid process and occiput above, to the scapula behind, and to below the clavicle in front. It was more prominent in front just anterior to the mid-point of the sterno-mastoid muscle. On dissection the swelling was found to consist of an unencapsuled mass of new growth. The mass extended from the mastoid process down to the first rib, and behind as far back as the scapula. It surrounded the clavicle and was infiltrating the deep fascial planes of the neck and the prevertebral muscles. Posteriorly the skin also was infiltrated by growth. The carotid sheath was completely surrounded, likewise the subclavian vessels and the upper cords of the brachial plexus. The lymph glands of the area were themselves enlarged and infiltrated by growth. In places the growth was of a purplish colour. There was oedema of the mucous membrane of the left arytenoid process. The oesophagus was pressed upon but not occluded by the growth. There was no sign in the mouth, pharynx, or larynx of any primary focus. The clavicle and first rib, though surrounded by growth, were not invaded by it. The mediastinal glands were not enlarged. The viscera showed no secondary deposits and no noteworthy abnormalities.

On microscopic section the growth proved to be an endothelial sarcoma of high malignancy.

The mass of growth removed *post mortem* was roughly conical, with a vertical measurement of 6 in. and a base of 4 in.

The prominent clinical feature of the case was the rapidity of growth of the tumour, an increase visible from day to day. The importance of the case from the medico-legal point of view is illustrated by the verdict of the coroner's jury, which was as follows: "Death was due to a cancerous growth in the neck caused by an injury sustained in the course of his work." Medical evidence had been given to the effect that the injury was responsible for the rapid increase of the tumour, but probably not for the occurrence of the tumour.

E. J. BRADLEY, *M.C.*, M.D., F.R.C.S.,
Surgeon, Staffordshire General Infirmary.

Reports of Societies.

MEDICAL INDICATIONS FOR INDUCTION OF ABORTION.

THE meeting of the Medical Society of London on March 25th, with Dr. J. W. CARR in the chair, was devoted to a discussion on the medical indications for the induction of abortion and premature labour.

Mr. EARDLEY HOLLAND, in opening, touched first on the medico-legal aspect. The law regarding abortion was compressed in a paragraph in the Offences Against the Person Act, 1861, where it was laid down as unlawful to procure or attempt to procure abortion except with the object of saving the mother's life or of avoiding serious injury to her health. The medical profession was entrusted with very generous powers. It had never been possible to lay down strict rules as to the medical indications, and if it had been possible they would have required constant change in accordance with the march of medical science. Diabetes, for example, was once an absolute indication, but since the introduction of insulin diabetic women could with little risk pass through pregnancy and labour. Some people thought that during the past few years there had been a lowering of the professional standard of responsibility with regard to the induction of abortion, but for his own part he believed the medical profession to be just as honourable a body of men as ever. It was necessary to clear the mind of conscious or unconscious prejudice. The detailed discussion of the medical indications, Mr. Eardley Holland said, he must leave, with the true modesty of the modern gynaecologist, to his medical colleagues. The old gynaecologist would have considered himself perfectly competent to pass judgement, but the younger generation of gynaecologists were not so competent, their leanings being more towards surgery and less towards medicine. The positive indications about which there was more or less general agreement were few in number; beyond these there were a large number of debatable indications, and beyond these again a heterogeneous collection of medical, social, and personal states which could not be classified. Among the more or less positive states he mentioned acute and chronic nephritis, chronic valvular disease of the heart, advanced pulmonary tuberculosis, Graves's disease, and insanity. Among the debatable indications which had come his way were hypothyroidism, hyperthyroidism, certain cases of cardiac disease, less advanced pulmonary tuberculosis, albuminuria or eclampsia in a former pregnancy, severe mental and nervous disturbance in early pregnancy following upon a difficult and dangerous previous confinement, and multiple arthritis deformans, which seemed to be made worse by pregnancy. Then came a little group of indications which might be termed eugenic, including refractory syphilis in the mother, and idiopathic epilepsy—rather flimsy in itself, but, like other indications of the kind, accompanied by social and economic considerations which just turned the scale. Lastly, there were cases which depended not on one indication but on a conglomeration of circumstances. In one case, for example, the patient, aged 45, was suffering from debility following a severe operation for infected gall-bladder, and had a bad family history of tuberculosis. In another case, in addition to a very poor condition of the mother, the father was a mental degenerate, and was said to have seriously injured a former child. The induction of abortion was an uncommon operation both in hospital and private practice, though more uncommon in the former. At the London Hospital between 1924 and 1927, out of 4,000 gynaecological operations, 31 were for the induction of abortion, the indications in nearly all the cases coming within the positive group. In his private cases since 1919, out of about 3,500 patients seen, he had performed the operation for inducing abortion on 28 occasions. The proportion of cases dealt with on what he called positive indications was smaller in private than in hospital practice, and a certain number, carried out at the instance of colleagues, fell within the class of what he had described as debatable indications, on which in the abstract perhaps not everyone would agree, but each case had to be considered strictly on its merits, with due regard to the responsibility placed in the hands of the medical profession.

Dr. B. T. PARSONS-SMITH dealt with the cardiological aspect of the question, passing in review some considerations on the termination of pregnancy in heart disease. He emphasized the serious consequences which pregnancy imposed upon such patients. In the most favourable circumstances additional circulatory strain was inevitable, and the process of pregnancy materially prejudiced the circulatory reserve and favoured the development of decompensation. At Queen Charlotte's Hospital, over a period of fifteen years, the total of 196 cardiac cases were admitted. The pregnancy in 49 of these cases was artificially terminated as follows: induction of abortion, 5; induction of premature labour, 34; Caesarean section at term, 10. The total deaths for the whole "heart" group numbered 32, and for those in which the pregnancy had been artificially terminated, 10—namely, 2 following induction of abortion, 7 following induction of premature labour, and 1 following Caesarean section. It must be assumed that the majority of heart patients would develop some degree of failure during pregnancy, but that proper antenatal care would in most cases enable adequate compensation to be maintained. In a relatively small proportion of cases heart failure might be of so grave a character and so refractory to treatment as to threaten a serious if not fatal issue. This latter group was mainly composed of patients in whom auricular fibrillation and considerable enlargement complicated the underlying conditions of structural heart disease. In all these cases pregnancy constituted a grave risk. Decompensation might be regarded as inevitable, and, failing improvement under treatment, active intervention was justifiable. Every case must be judged on its own merits. One was justified in advising intervention in those cases in which heart failure, especially if it arose in the earlier months of pregnancy, progressed in spite of treatment, and equally in those patients where failure developed and there was a history of decompensation in previous pregnancies. Finally, it must be also remembered that the process of induction in patients with heart disease and failure might, and very probably would, itself constitute a serious maternal risk, as evidenced by the figures from Queen Charlotte's, which showed a mortality rate of 40 per cent. following induction of abortion, and 20 per cent. following induction of premature labour.

Dr. BERNARD HART, who spoke from the standpoint of a psychiatrist, said that the psychoses, or definite insanities, and the psycho-neuroses, or so-called functional nervous disorders, required independent consideration from the point of view of this problem. Psychoses occurring in association with pregnancy might be dealt with under three headings: (1) where a psychosis developed after the occurrence of pregnancy; (2) where pregnancy occurred in the course of a pre-existing psychosis; and (3) recurrent psychoses. With regard to the first group, it was formerly held that the psychoses developing during pregnancy and the puerperium were definite entities constituting special forms of mental disorder; this view had now been generally abandoned. So far as this group was concerned, it was clear that pregnancy was only a circumstance of minor importance, and its removal was not likely materially to affect the course of the disorder. Abortion was therefore not justifiable from the psychiatric standpoint. The second group comprised cases of exhaustion psychosis, a form of disorder in which toxic factors or emotional strains might play a

decisive part. In this group the pregnancy was a factor of definite causal importance, but it had generally been noted that the induction of abortion did not materially affect the course of the mental disorder. On the whole, cases arising early in pregnancy tended to recover before confinement; cases arising late in pregnancy, to recover after confinement. Psychiatrists were increasingly reluctant to recommend termination of the pregnancy in these cases for purely psychiatric reasons. The operation of abortion might itself act as a factor tending to accentuate an exhaustion psychosis. With regard to the group in which pregnancy arose in the course of a pre-existing psychosis, the considerations just mentioned applied with redoubled force. Abortion for purely psychiatric reasons was rarely justifiable. As for recurrent psychoses, two subgroups had been distinguished—one in which the former attacks of insanity had no relation to a pregnancy, and the other where a psychosis had developed in association with a former pregnancy or puerperium. In the first of these subgroups each case must be decided on its merits. Where several attacks had occurred, abortion would seem clearly justifiable on the ground that a continued pregnancy was likely to act as a source of stress. In the second subgroup the indications for abortion were weighty. Coming to the psycho-neuroses, the speaker said that this was a much more difficult field, and one in which there was no place for rigid principles or opinions. This was a sphere of disorders where psychological factors played an important part in causation, and amongst such factors the anxieties and fears centring around pregnancy might be of fundamental importance. Where there was a pre-existing psycho-neurosis, and where the effect of pregnancy was not itself a cause of any anxiety, there was *no indication for abortion*. There seemed no clear evidence that pregnancy brought special dangers in a psycho-neurotic case, except in so far as its existence aroused fresh distress, but there were a great number of cases in which the pregnancy gave rise to acute anxieties and conflicts. The induction of abortion here, no doubt, would relieve the symptoms and perhaps avert the development of a serious nervous breakdown. But the decision must rest on a question of degree, and nowhere could a well-marked dividing line be drawn. There was a series of cases where severe anxiety conditions passed over into clinical factors—a definitely melancholic type. Here the factor which dominated the problem at issue was the risk of suicide. In all these cases the attention of the psychiatrist must be focused upon the central problem of the probable effect upon the mental and nervous health of the patient of allowing the pregnancy to continue. But factors of many kinds had to be considered in determining this probable effect, and the final decision must depend upon the force and interaction of all these factors.

Dr. GEOFFREY MARSHALL said that he had followed up a small group of cases of pregnant women referred from an ante-natal clinic to the tuberculosis department of which he had charge. There was great difficulty in deciding in a given case whether it was a positive or a debatable indication. Certainly the cases could not be grouped according to the amount or the extent of lung involvement. Where a patient had been known to suffer from definite symptoms of pulmonary tuberculosis for a good many years, in spite of the fact that the lesions were fairly extensive, she might be expected to go through pregnancy and labour without any great harm, but where the disease was a recent one the condition might be expected to be worsened by pregnancy. Cases in which there was only a short history were picked out, and the gynaecologists were asked to terminate the pregnancy.

Dr. ANTHONY FEILING noted that among the positive indications mentioned by Mr. Holland there appeared Graves's disease. The speaker believed that if a patient with this disease became pregnant, which was rather unlikely to happen, she had a good chance of going through the pregnancy quite well. Another positive indication set out was acute and chronic nephritis, but this obviously depended very much on the severity of the condition, and he hoped it was not intended that in every case of acute nephritis labour must be artificially terminated. As to hypothyroidism, it was well known that patients with true myxoedema did not become pregnant at all; in milder degrees he could not see why it should be necessary to induce abortion. As for epilepsy, the number of cases of epilepsy affecting one parent in which it was justifiable to terminate pregnancy must be small. Only about 30 per cent. of epileptic persons had an epileptic heredity.

Dr. H. B. DODWELL asked whether severe paroxysmal asthma, incapacitating the woman every winter, would be regarded as an indication. Dr. T. C. CLARE spoke of a pregnant woman who had a single kidney. Was this an indication for abortion? Dr. J. W. CARR, from the chair, said, with regard to phthisis, that in his early days it was believed that during pregnancy phthisis tended to remain quiescent, but flared up acutely after parturition. Was there any danger of an acute "flare-up" after the induction of abortion?

Mr. EARDLEY HOLLAND quite agreed with Dr. Feiling about myxoedema. With regard to single kidney he would certainly have induced abortion. He appreciated what Dr. Parsons-Smith had said about heart conditions, and considered it wonderful how patients with severe cardiac disease passed successfully through labour. Dr. PARSONS-SMITH said that the large majority of women suffering from cardiac conditions would, with adequate rest, pass through pregnancy in normal fashion. Dr. BERNARD HART devoted his reply to discussing the assessment of the risk of suicide in psycho-neurotic pregnant women.

INDUSTRIAL DERMATOSES.

THE Sections of Dermatology and Epidemiology and State Medicine of the Royal Society of Medicine combined, on March 21st, for a discussion on "Industrial dermatoses, their causation, recognition, prevention, and treatment." A large exhibition of photographs of skin conditions due to occupations was provided by Dr. R. Prosser White, Dr. W. J. O'Donovan, Dr. S. A. Henry, Dr. H. A. Cookson, and others.

Dr. J. M. H. MACLEOD, who occupied the chair, said that no more than the fringe of the subject could be touched, but if the discussion excited a keener interest in the problems of the industrial dermatoses it would have served its purpose. The recognition of injuries to the skin from contact with irritants as a result of occupation dated far back in the history of medicine. He had before him a translation by the present President of the United States of a monumental work published in the middle of the sixteenth century by Agricola. In this book the author pointed out the dangers of ulceration from contact with corrosives. Occupational dermatitis did not figure largely in the literature of this country until 1775, when Percival Pott wrote his classic paper on chimney-sweep's cancer, but so far as the speaker could make out it was really Robert Willans who gave the first systematic description of occupational dermatitis, describing the psoriasis palmaris of shoemakers, a dermatitis in metal workers, grocer's itch, and washerwoman's eczema. Since those days the subject of occupational dermatoses had become familiar, and workmen's compensation and industrial insurance had given it an almost exaggerated prominence. There still remained many unsolved problems, and the cause of some of these conditions was still obscure. It was not known, for example, whether baker's itch was due to the flour or to imperfect cleansing methods by the workman. Then there were the problems of idiosyncrasy and allergy as factors in causation. There was some tendency for cases to be labelled occupational dermatoses when in fact the true cause was some pre-existing skin disease or congenital defect. He hoped that the debate would be the means of causing more co-operation between the dermatologist and the industrial physician. He added that this was the first occasion on which a discussion at the Royal Society of Medicine had been opened by a lady; Dr. Sibyl Overton, as medical inspector of factories to the Home Office, had had exceptional opportunities of studying occupational dermatoses at first hand.

Dr. SIBYL OVERTON said that it was being realized that the subject of industrial dermatoses was of the greatest importance both to the individual and to the nation. Through dermatitis, industry might lose many thousand man-hours daily, as well as huge sums in compensation.

Was the increase of dermatitis in industry real or apparent? A vast and increasing number of irritants were used in industry capable of producing dermatitis. The classification of dermal irritants according to their type of action was only partly practicable; there often was a multiplication of modes and causes. Injury to, and separation of, the horn cells was the keystone of industrial dermatoses. The causative agents voluntarily reported to the Home Office each year revealed a steady increase. Alkalis had headed the list for the last three years. Of the industries concerned, engineering had reported the greatest number of cases for this period. The ages and previous history of workers reported as affected with dermatitis in 1928 showed the highest percentage of recurrent cases in males over 50, while a very large number of primary cases occurred in workers under 30. The speaker gave an account of special inquiries into dermatitis in certain industries—namely, baking and flour confectionery, biscuits and sugar confectionery, french polishing, calico bleaching, printing, and dyeing. Of 400 bakers and pastrycooks whom the speaker had examined in various parts of the country, only 12 were suffering from dermatitis, 9 being bread bakers. Only three cases, all slight, occurred among machine mixers of dough. Methods of removing staining from the skin were often highly productive of dermatitis. There was need for increasing knowledge of harmless and effective methods of cleansing the skin in certain industries. Experience had shown the following means of prevention to be effective, their common object being to protect the integrity of the horn cells: (1) emollients before and after work; (2) complete removal of the irritant by harmless methods after work; and (3) inspection of hands and arms by an experienced observer, with a view to enforcing early treatment of minor injuries, such as cuts and burns, scrupulous cleanliness of hands and arms and of overalls, and removal from irritants and prompt treatment for early cases.

Dr. WILLIAM DYSON commented on the type of trade dermatitis which clinically and histologically was indistinguishable from cases usually classified as eczema. It was defined as a superficial non-microbic inflammation of the skin caused in all cases by external irritation in a predisposed subject. He did not recognize any difference between this type of case and eczema, except that the former occurred in a manual worker. The predisposing causes were hyperidrosis, xeroderma, and ichthyosis, senile degenerative changes in the skin, debility, tuberculosis, and anaemia. Relapses were frequently seen, and the cause underlying this liability to recurrence brought into discussion the complicated problem of sensitization. Sensitization to a specific irritant, such as one saw in primula dermatitis, was extremely rare in trade dermatitis, but a general hypersensibility of the skin after long-standing or repeated attacks of dermatitis was common. He held that absorption of toxins from damaged or inflamed epithelium was the causative agent in the production of this hypersensibility. With the object of trying to find scientific data in support of this theory, he had had blood sugar estimations made in over fifty cases. These cases were selected from a number which showed sensitization by having evidence of dermatitis in other parts than the areas exposed to irritation. The results of the investigation suggested: (1) that when sensitization was present a high blood sugar figure was to be expected; (2) that when the products of inflamed epithelium were being absorbed one found on the average a higher blood sugar content than when those products were being discharged on the surface. Thinking that this hypersensitiveness might be an anaphylactic phenomenon he treated a number of patients with injections of their own blood with the object of producing an anti-anaphylactic state, and he described the results obtained. As for prognosis, this was good in a first attack, providing no obvious predisposing causes were present, but bad if the case was of long standing or there had been repeated attacks. It was especially bad if the dermatitis developed in a man who had been working at his trade for many years before he had his first attack. The means of prevention were medical examination before a man was employed and the periodical inspection of all employees.

Dr. HOWARD MUMMERY described his experiences as medical officer to a large catering firm with 5,000 employees, contending that watchful care kept the incidence of occupational dermatoses low. Apart from regular inspection, and application of suitable treatment in early cases, it was important to exclude people from occupations for which they were not fitted. The dry, inelastic skin predisposed to the occurrence of eczema and other skin conditions, and the fissuring allowed the entry of pathological bacteria. He contended that there was no pathological lesion peculiar to bakers. In the factory mentioned dermatitis was of low incidence and steadily decreasing.

Dr. H. MACCORMAC said that the most difficult group to understand were the non-specific eruptions, generally eczematous, which occurred in people who worked at a variety of occupations. The eczema occurred during work, but whether caused by the trade was a matter of dispute. He described an investigation into the dermatitis found among photographers; he thought metol largely to blame.

Sir THOMAS LEGGE approached the question sympathetically from the standpoint of the worker, and said it was the duty of the medical man to inform the sufferer from occupational dermatosis that he could make a claim for compensation through the certifying factory surgeon for his district. The speaker related some of his experiences while he was an inspector of factories.

Dr. W. J. O'DONOVAN feared that if the matter had been solely in the hands of professional dermatologists the great mass of occupational dermatitis would have remained largely undiscovered. Now, however, he thought the pendulum was swinging in the wrong direction, and that the figures were grossly inflated. Many certifying factory surgeons were content to certify cases without reference to dermatologists; but the chief increase was attributable to the incursion of administrators, lawyers, and accountants; hence financial interests loomed large. He feared it was sometimes the worker's mind which was sensitized rather than his skin.

Dr. PROSSER WHITE stressed the importance of knowing the physico-chemical action on the skin of the particular drug or irritant at fault in order to deal adequately with these cases. He agreed that the chief skin injury in occupations was caused by alkali, since that was the most used dirt and stain solvent. The question of sensitization was very difficult, and he thought the modern tendency was not to emphasize sensitization so much.

Dr. ALLAN PARSONS said he had been chiefly interested in baker's itch, a subject on which he had conducted an investigation for the Ministry of Health; but Dr. Overton's address showed that this subject could well be left to the care of the Home Office. There were some interesting cases of dermatitis in hop-pickers. He found that most of the "hoppers" suffered from abrasions and cracks due to pulling the hop flowers off the vines. They had a papular and pustular erythema, with extreme irritation of hands and forearms, and in many cases the face was affected. The same people suffered from the condition year after year. The condition was not very severe; 52 patients attended hospital for treatment for a total of only 81 days.

Dr. LANCASHIRE analysed 100 cases of trade dermatitis which had come under his attention; 13 per cent. of these were not due to trade conditions, though they had been certified as such by the factory surgeon; 20 per cent. were due to exposure to aniline dyes; and 7 were cases of baker's itch, which he regarded as a genuine condition peculiar to bakers and confectioners, and caused invariably by handling the dough. He was sure some of these people were directly sensitive to the handling of dry flour. Eighteen cases occurred among rubber workers, and 8 of these were in rubber tyre builders.

Dr. F. E. FREMANTLE, moving a vote of thanks to the speakers, said he regarded the discussion as a most notable one, and one which was important from the point of view of future legislation, at a time when the State took an increasing interest in helping to insure the worker against accidents in ordinary life. The desire, however, was open to great abuse; definitions were apt to be framed and accepted without due regard to the medical aspect.

Reviews.

FUNDAMENTALS OF SURGERY.

MR. H. S. SOUTTAR has written a textbook of surgery which has many unusual aspects. In his very title, *The Art of Surgery*,[1] the author challenges criticism. "Surgery," he says, "is essentially an Art, for it demands of those who would pursue it a combined dexterity of hand and eye, and an instinctive perception of values, which are the characteristics of the true artist." Dexterity of the eye (a questionable use of words) may be a necessary attribute of a practised craftsman of surgery, but even this will not convert him into an artist, for few would maintain that the surgeon is the creator of any new moral or spiritual experience, which alone distinguishes "the true artist" from his fellow craftsmen. It seems ungrateful to carp at Mr. Souttar's title-page, for this can scarcely affect the value of the contents of the book; yet it may be important to avoid any exaggeration of the surgeon's claims to be a superior person. The values that he learns to perceive are material values, and he is therefore not an artist. It is on this basis that patients are willing to entrust their bodies to his hands. His craftsmanship must be guided and supplemented by intellect, and it is only in the laboratory that he may give rein to the processes of the imagination.

Mr. Souttar is well known to be a sincere, balanced, inventive, and expert craftsman, and the excellence of his book is further proof of this. He is justly appalled at the bulk of the accumulated experience which has to be brought to bear upon modern surgery, and he seeks to lighten the student's burden by describing fully only what is fundamental. Other writers of textbooks have attempted, with varying success, the same process of sifting, but none have had the wit to devise so excellent a method of driving their words home by means of the marginal illustration. The page has to be somewhat large to accommodate the text with margin wide enough for even small drawings, and unless these margins are fully used much space is wasted. This is, in fact, the only possible criticism of Mr. Souttar's method, that he has not carried it far enough, for several hundreds of additional drawings might usefully find a place in the many blank margins. Any student, however, with any capacity for drawing might get much amusement and profit by adding his own diagrams and illustrations. The book contains in addition twelve coloured plates, which are of small value, though they probably add much to the cost of the book. There seems to be a belief among publishers that coloured plates help to sell a textbook, though it may be doubted whether this is really so except in the case of works on dermatology. Most students would be more influenced by a reasonable price than by a few coloured plates on unpleasant shiny paper. Mr. Souttar clearly does not suppose them to be of great importance, as he nowhere provides any list or index of illustrations, and we would ask him to consider omitting them from the next edition. There will assuredly be another edition, for the book is comprehensive, "up to date," practical, and attractively written, so that it cannot fail to find a large number of readers. The margins are used for the headings of the subject-matter as well as for the drawings, so that there is no interference with the continuity of the text. The book is consequently much easier to read than are most textbooks, and this feature, combined with the visual emphasis provided in the margins, should relieve many students of the necessity for using any sort of "cram-book" when once they have familiarized themselves with Mr. Souttar's survey.

It was a bold undertaking to start once again on the "one-man" book in this age of specialization and composite pictures, but the gains given by the resulting cohesion of the chapters and absence of repetition more than outweigh any possible objections. Mr. Souttar will no doubt wish to alter some of his statements in future editions. It seems unlikely, for instance, that he really believes that traumatic myositis ossificans only causes "a little stiffness," and that treatment is rarely required. Other matters of detail will be brought to his notice by his friends, and need not be specified here. Of greater importance is a criticism that may be levelled at Mr. Souttar's descriptions of the various forms of cancer and the means of diagnosing them. In our view any modern textbook of surgery should insist almost to the point of boredom on the necessity for diagnosing cancer before it possesses all the characters by which it is usually recognized. No student, for instance, would understand from a reading of Mr. Souttar's description of cancer of the breast that it is frequently seen in a stage when it shows perhaps only one of the features presented at a later stage, and further, that the prognosis depends so much on early diagnosis that mistakes must be made in the direction of suspecting a lesion which is not carcinoma. This is much the gravest criticism which we have to make of Mr. Souttar's book, for the importance of early diagnosis of cancer cannot possibly be exaggerated, and it should be drummed into the rising generation of medical students by the spoken and the written word until it becomes impossible for him to forget it.

If, however, Mr. Souttar's book has some defects of this kind they are only such as it shares with most others that are available. In many respects *The Art of Surgery* makes a real advance in the succession of textbooks, and we recommend it to all students, and to any practitioner who wishes to be abreast of the times.

[1] *The Art of Surgery.* By H. S. Souttar, D.M., M.Ch.Oxon., F.R.C.S.Eng. London: W. Heinemann (Medical Books) Ltd. 1928. (Cr. 4to, pp. 624; illustrated. 30s. net.)

TWEEDY'S "PRACTICAL OBSTETRICS."

A SIXTH edition of Hastings Tweedy's *Practical Obstetrics*[2] has been recently published by the Oxford Medical Publications. This popular manual has been revised and largely rewritten by Dr. BETHEL SOLOMONS, who is now alone responsible for the text. As in the case of previous editions, the main consideration has been to present the methods so successfully practised in Dublin at the Rotunda Hospital, but the teaching of other schools has not been ignored. As was to be expected, the present Master of the Rotunda discusses his subject in a forcible, straightforward manner, which never leaves any room for doubting what line of treatment he recommends. The different problems of obstetrics are fairly presented, and the recommendations for dealing with them unequivocably stated, the wealth of Dr. Solomons's experience being sufficient guarantee of the practical utility of the advice given. All the chapters have been brought thoroughly up to date, and the results of the author's experience of some of the new methods of treatment of accidental haemorrhage and puerperal sepsis are clearly set forth. Dr. Solomons is a strong advocate of lower segment Caesarean section, but the difficulties of this operation for the less experienced operator are not minimized. A new chapter has been added on the use of x rays in obstetrics with appropriate illustrations. Apart from these the author has wisely chosen his illustrations from block drawings and diagrams which are without exception clear and to the point. The practical teaching of this book has always been its strong point, and Dr. Bethel Solomons has faithfully followed tradition by keeping on the same sound lines.

[2] *Tweedy's Practical Obstetrics.* Edited and largely rewritten by Bethel Solomons, M.D., F.R.C.P.I., M.R.I.A. Sixth edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Demy 8vo, pp. xii + 739; 284 figures. 25s. net.)

ANATOMY FOR STUDENTS.

As a technical achievement the *Pocket Atlas of Anatomy*[3] by PAUCHET and DUPRET is worthy of the highest commendation. Within the limits of so small a volume are contained 297 plates illustrating most regions of human anatomy. The plates consist of line drawings, in some cases coloured, which are remarkable at once for their simplicity, clarity, and general accuracy. Some of them also display a welcome spirit of originality, and illustrate dissections viewed from an unusual angle. An atlas of anatomy, to justify its production, must possess at least

[3] *Pocket Atlas of Anatomy.* By Victor Pauchet and S. Dupret. Oxford Medical Publications. London: Milford, Oxford University Press. 1928. ($4\frac{1}{2} \times 7\frac{1}{2}$, pp. vi + 306; 297 plates. 12s. 6d. net.)

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT.

(*Concluded from page 567.*)

II.

General Vitamin Studies.

Work by Professor Drummond at University College on the chemical nature of vitamin A as it occurs in various fish-liver oils has nearly been completed. It has now been shown that practically the whole of the vitamin fraction of cod-liver oil represented by the non-saponifiable portion can be separated into components in a chemically pure condition. From the purely chemical examination of the highly active concentrate from cod-liver oil and other fish oils it is probable that the vitamin constitutes much less than 1 per cent. of the whole material—that is, a ten-thousandth part of the original cod-liver oil. This work has been concurrent with an extensive investigation of the vitamin value of commercial preparations of cod-liver oil undertaken with the aid of a grant from the Empire Marketing Board. Other work by Professor Drummond suggests that the so-called vitamin B complex owes its action, not as now believed to two substances, but to four. At the Field Laboratories, Cambridge, Drs. L. J. Harris and T. Moore have found that large excess of cod-liver oil added to an otherwise satisfactory diet may in fact be injurious to the rat, and this study is being linked with observations on the beneficial effects of an increased allowance of the vitamin B complex. At King's College for Women Professor Mottram and Dr. Hartwell are investigating the relative values of brown and white bread in a diet arranged to imitate that of an agricultural labourer. Dr. Hartwell has also continued her work on the relations of vitamin B to lactation.

Dental Disease.

Dr. E. W. Fish has been investigating the minute structure of teeth, the circulation in them of lymph, and the relation of these to dental disease. Mrs. Mellanby has continued her researches at Sheffield into the structure of children's teeth, and the results, taken in conjunction with those of certain animal experiments, suggest that the fundamental cause of the prevalence of dental caries is a defect of nutrition. An important investigation has been started at Birmingham, where children in three institutions are receiving special additions to their ordinary diet with a view to determining the influence of these on the development of teeth and liability to dental caries. At the London Hospital Mr. J. R. Marrack has found that low calcium in the saliva is distinctly more common in patients with numerous carious teeth, and at Guy's Hospital Mr. A. Bulleid is investigating the possible role of anaerobic bacteria in apical infection of the teeth.

Cardio-Vascular and Excretory Systems.

Dr. J. C. Bramwell and Dr. R. Ellis took part in the studies made at Amsterdam of Olympic athletes, and in particular paid attention to the circulatory mechanism in the long-distance runners. At Cambridge Dr. G. V. Anrep is studying the coronary circulation in the heart by a method which indicates to what extent the cardiac contraction itself may favour or hinder the coronary circulation. Dr. A. A. Osman, at Guy's Hospital, continues his work on the treatment of nephritis by alkalis, whereby further evidence of the efficacy of alkalis in the treatment of anuria has been obtained, and some light has been thrown on the mode of action of alkalis in causing diuresis. With the help of Dr. H. G. Close he has found that the plasma bicarbonate content forms a useful means of differentiating between acute focal and acute diffuse nephritis and between the former and some other causes of haematuria. Dr. G. A. Harrison, at St. Bartholomew's Hospital, has investigated indican retention in the blood in cases of uraemia, but, while the cause of an obscure colour reaction has been elicited, no light has been shed on the causes of uraemia.

Nervous and Mental Disorders.

At Oxford Dr. D. Denny-Brown has continued his work on the problems of reflex posture, and has investigated some related problems of the structure of nerve endings in muscle with special regard to the innervation of muscle by the sympathetic nervous system. At the National Hospital, Queen Square, London, Dr. E. Blake Pritchard is making an experimental study of the knee-jerk by means of optical records under variations of stimulus and in different pathological conditions, and at the same hospital Dr. M. Critchley is working on certain nervous manifestations which occur in cerebral arterio-sclerosis. In the Scottish Asylums Research Laboratory Dr. F. E. Reynell continues his investigations on the paths of infection of the brain, meninges, and venous blood sinuses from neighbouring inflammatory foci, and with Mr. Logan Turner has studied three cases where the primary focus was in the accessory air sinuses. Dr. F. A. Pickworth in Birmingham has made a further investigation of the abnormal agglutinin reactions which occur in the insane, and at Cambridge Miss L. G. Fildes has completed her inquiry into the special psychological causes underlying the condition known as word-deafness and has also made an experimental study of the discriminative power of defective boys.

The Blood and Glands of Internal Secretion.

In Professor Barcroft's laboratory at Cambridge a collaborative examination has been made of the different methods of estimating the oxygen capacity of human blood with a view to elucidating a slight discrepancy between the results obtained by American and British workers. At Charing Cross Hospital Dr. A. B. Rosher has found that there is no experimental evidence of intravascular haemagglutination following the intravenous administration of horse serum. Dr. Stanley P. Davidson in Edinburgh has continued his study of various aspects of pernicious anaemia, and, in particular, has investigated the bacteriology of the gastro-intestinal contents. He finds no bacteria which are not normally present in healthy people, but, on the other hand, certain organisms, especially *B. welchii*, are present in a greater proportion in the faeces of cases of pernicious anaemia. At the Lister Institute Dr. V. Korenchevsky has continued his study of testicular hormones. The aim of the experiments is to use glands having the largest amount of the special secreting tissue, and at the same time devoid of generative tissue. Some direct evidence has been obtained to support the common theory that the degeneration of generative tissue in cryptorchid animals is chiefly due to the higher temperatures of the sexual glands within the abdomen than when descended to the external position. Dr. A. S. Parkes has progressed with his work at University College on the ovarian secretions. The corpus luteum has been shown to be essentially responsible for the characteristic changes of the post-ovulation period of the cycle, including the complete development of the mammary glands during pregnancy, a process in which the foetus has been shown to play no part. Further work on Graves's disease by Drs. Williamson and Pearse has led to the finding of a method by which the two secretions of the thyroid gland can be separated so that their biochemical, physiological, and clinical activities can be studied. The relation of Graves's disease to iodine metabolism has been investigated, and colloid secretion, which contains all the iodine, has been shown not to be responsible for the toxic factor in this disorder. Dr. R. D. Lawrence's work on diabetes and insulin has recently enabled him to show that the usually accepted quantitative relationship between insulin and glucose does not exist. The normal ratio of dosage of insulin to carbohydrate used up is found only to hold good up to a certain point, beyond which relatively small increments of insulin can enable the body to dispose of increasingly large amounts of carbohydrate. At Sheffield Dr. G. A. Clark has done some work which indicates that possibly the vagus nerve exercises a tonic inhibitory effect on insulin secretion.

Tuberculosis and other Infections.

Dr. A. Stanley Griffith, studying the immunizing value of the B.C.G. vaccine of Calmette and Guérin, while unable to confirm the work of Wilbert on the production of immunity to tuberculosis in monkeys, has been able to show that immunity can be produced in the calf by intravenous, subcutaneous, or oral administration of the

accine. Dr. J. W. S. Blacklock in Glasgow has studied twenty cases of fatal tuberculosis, bringing the total numbers in which the infecting organism has been isolated up to eighty-four. In primary pulmonary tuberculosis 96 per cent. of cases are due to the human type of organism. Work on haemolytic streptococci and the infection due to them has been continued under the supervision of a special committee, of which Sir Frederick Andrewes is chairman. A close correlation between a Dick-positive reaction and the subsequent development of puerperal sepsis was found among a hundred prospective mothers, and arrangements are being made to render cases immune to puerperal fever before labour. Dr. L. Colebrook has completed one phase of his work on the arsenical compounds in relation to the chemotherapy of streptococcal infections, and a careful clinical trial is now to be made of the influence of these compounds, principally derived from salvarsan. Study of some of the problems of Hodgkin's disease is being carried on at St. Bartholomew's Hospital under the terms of the Rose Bequest, and a combination of clinical and pathological workers is conducting investigations. The work of the Council on canine distemper, largely made possible by the *Field* Distemper Fund, has now reached a stage where the knowledge acquired is capable of being applied to the production of immunity. Trial of the methods has been made upon dogs kept under ordinary conditions, and wherever a clear comparison has been possible between inoculated and uninoculated dogs the results have been strikingly successful; evidence is lacking only as to the duration of the immunity conferred.

CANCER, RADIOLOGY, AND RADIOTHERAPY.

Studies of cancer at the National Institute by Dr. Gye have been continued. At St. Mark's Hospital Mr. W. B. Gabriel is following up and indexing the after-histories of cases of cancer of the rectum, and Dr. Cuthbert Dukes is grouping cases in which the rectum has been excised, according to the depth to which malignant cells have penetrated. Dr. Helen Chambers at Middlesex Hospital has made further investigations into the effects of tumour products on tumour growths. After tumours have been given a lethal dose of x rays *in vivo* it has been shown that the antigen causing immunity is absorbed in minute quantities spread over several days, and its isolation in concentrated solution is therefore a difficult problem. At Cambridge an investigation into the Shaw-Mackenzie serum test for cancer has been completed. The test was negative in certain cases of cancer, and positive in many other conditions. The biological effects of radiation are being studied by Dr. H. A. Cowell at King's College Hospital, and in particular he is investigating the effects of radiation upon patients with malignant disease to whom fluorescein has been administered.

VISION AND HEARING.

Under the direction of the Committee upon the Physiology of Vision research dealing with problems of the fighting services has been continued along with other investigations of more general interest. Work at Cambridge under Mr. F. C. Bartlett has been concerned with the visual perception of form and movement in the peripheral field of the retina, and in the same laboratory Dr. D. N. Buchanan has continued his investigations on flicker, which has also been the object of research at University College, London, where, under the direction of Dr. R. J. Lythgoe, the effect of light and of dark adaptation on the performance of certain tasks has been studied. All this work has obvious practical interest in relation to the driving of motor cars at night and to some special problems of industry. Dr. W. S. Duke-Elder and Mrs. Duke-Elder at the same College are continuing their work on the physiology and pathology of intraocular pressure. They have discovered that the vitreous humour plays an unexpectedly large part in the control of this pressure, and with Miss Adams a study of the calcium content of the lenses and the blood in cases of cataract has been completed. A second committee has been at work with analogous functions, but concerned with hearing.

PHYSIOLOGY, PATHOLOGY, BIOCHEMISTRY.

General researches in these subjects have been carried on at various centres during the year. At Leeds Dr. H. W. Davies has been investigating oxygen administration, and from a study of the effects of injections of oxygen upon the oxygen saturation of the arterial blood, he has shown that injection of oxygen does not relieve oxygen-want in human patients. At Glasgow Dr. Munro Cameron is examining the pathological basis of nervous affections of the oesophagus, with special reference to spasmodic conditions of its upper and lower ends. Ten fatal cases of cardiospasm have been examined, and it has been established that a degenerative lesion of the intermuscular nerve cells is usually associated with the clinical condition. Dr. R. A. Webb has been working with Professor Dean at Cambridge upon the precipitin reaction. Dr. L. E. H. Whitby, at Middlesex Hospital, has been investigating the bactericidal effect of radium in relation to fluorescence, and has found that beta rays are as strongly bactericidal as x rays and gamma rays. The investigation of two typhoid carriers in Glasgow by Dr. K. Guthrie has shown removal of the gall-bladder in intestinal carriers to be effective treatment. Mr. A. Wormall has shown that ultra-violet rays have a destructive action on the haemolytic power of serum *in vitro*. This action has been studied further, and the destruction is attributed to alterations in the protein components of the complement. Dr. William Robson is studying the part played by tryptophane in the animal organism.

ANAESTHETICS.

The Anaesthetic Committee has continued to collect information about the highly dangerous "late ether convulsions," but so far no adequate explanation has been forthcoming. During the year an inquiry was received from New Zealand as to an impression strongly held there by anaesthetists that ethers made in the British Empire are inferior in anaesthetic value to those originating in Germany and the United States. By suggesting certain tests the committee were able to convince the hospital authorities concerned that this impression has no foundation in fact. Certain research has also been undertaken with regard to the trial of "avertin" for rectal administration.

EPIDEMIOLOGY.

Work on this subject under the joint direction of Professors Topley and Greenwood has been continued, and the mouse population which has now been under continuous observation for eight years is being maintained by daily additions of normal mice, while other long-continued epidemics are being studied. It is hoped to reach a definite conclusion with regard to the importance of natural immunization as a factor in herd-immunity. Another subject which has been studied is the possibility of obtaining knowledge of the vital statistics of mice not deliberately exposed to infection.

STATISTICS.

Work under this heading covers a very wide field, for, in addition to special problems, the staff concerned with this subject is often called upon to study the results of other workers. The Statistical Committee also serves the Ministry of Health in the field of medical statistics. In this connexion one of the most important pieces of work in hand is the analysis of anthropometric data collected for a committee of the Board of Education presided over by Sir George Newman. During the past year Mr. Matthew Young has made a study of the racial significance of blood grouping, and the results seem to indicate that too much importance has been attached to blood group distribution as a criterion of racial classification.

INDUSTRIAL MEDICINE AND INDUSTRIAL FATIGUE.

Miscellaneous researches into industrial problems have been continued, and many of these are discussed at greater length in the annual report of the Industrial Fatigue Research Board. The present report mentions some work on miners' nystagmus, particularly in connexion with the illumination of mines, while the psychological aspect is to

be investigated under a scheme being prepared by Dr. Millais Culpin. A study of the sickness incidence in certain spinning mills is being undertaken with reference to the dusty atmosphere of certain rooms, while some of the problems of load carrying by dock and transport workers are receiving attention.

Concluding Notes.

In its last pages the report gives an account of the work done by holders of the travelling fellowships endowed by the Rockefeller Foundation, and records that these fellowships have been renewed for a third period of three years by the Foundation. The Council expresses its appreciation of the work done by Sir Hugh Anderson during the short period he served on the Council before his death, and records also the loss to the field of physiological research occasioned by the death of Professor Noël Paton. The Council, in conclusion, expresses its gratitude for financial aid it has received from public bodies and private benefactors, which has enabled it greatly to enrich its programme and has rendered certain aspects of its work possible.

THE MENTAL HOSPITAL OF TO-DAY.

Lecture by Sir C. Hubert Bond.

Sir C. Hubert Bond delivered a lecture to the National Council of Mental Hygiene on March 20th on "The mental hospital of to-day." He found some fault with this title because the treatment of mental patients and mental hospital administration generally were advancing so rapidly that no institution could be said to be the mental hospital of to-day. A plan for a new mental hospital in harmony with present-day requirements might be approved, but before the work was completed the general idea as to what a mental hospital should be would have gone on ahead. He disliked also the term "mental hospital." His personal preference was for the old word "asylum," which had quite a good connotation if one studied it, though he agreed that if mental hospitals could be spoken of simply as "hospitals" it would be better still. Other hospitals were not usually labelled according to the conditions they treated, and it would be much better to call a mental hospital after a saint or a locality, and to drop the adjective. In official documents the words "for mental disorder" might be retained, in small type, but it was injudicious to announce to the world and to prospective patients the exact nature of the hospital.

Mental and General Hospitals Compared.

Sir Hubert Bond went on to explore the differences between a mental hospital and a general hospital. If one had regard to the older mental hospitals established in the early nineteenth century it must be said that there was a vast difference, but he doubted whether there need be any great difference, and he considered that the two institutions were becoming much more similar. There was one necessary difference, due to the fact that general hospitals did not usually keep their patients for any long period, *whereas many mental cases had to have institutional care*, not in beds, for years; the ward provision in the two kinds of institutions must therefore be dissimilar. Only one general hospital in the country, so far as he was aware, had wards for mental cases—namely, Middlesex Hospital; the wards were small, but he hoped they would be enlarged. The modern general hospital, again, like the mental hospital, was more and more inclined to remove from the towns into the country, leaving a nucleus for emergency cases. He saw in the future the general hospital taking more the administrative pattern of the mental hospital, and the mental hospital shedding some of its ancient features. In one respect a mental hospital was more of a general hospital than a general hospital itself. *The general* hospital expressly excluded certain cases—fevers, for example, and, save in the one instance mentioned, mental cases. The mental hospital, on the other hand, had to provide for all cases of general illness among its mental patients. Whatever the illness from which a mental patient suffered, he could not be turned out of the institution.

Classification of Patients.

The new Middlesex County Mental Hospital and Colony at Shenley, a plan of which he exhibited, afforded Sir Hubert Bond an illustration of the general lay-out of the modern mental institution. Cases on admission were received at a central building, which was arranged so as to separate different classes of cases. The depressed and quiet patient, for example, saw and heard nothing whatever of the patient who was excited and delirious. Little villas or convalescent homes were provided in one part of the grounds for those who were recovering, and here there was no need for any patient to realize that he was not in an ordinary institution for the sick. About 30 per cent. of the patients were transferred to these homes. Another batch of patients came in, unhappily, to die swiftly; these were accommodated, on the county of Middlesex plan, in one or two most beautiful sick wards; when these were completed there would be no better hospital wards anywhere. Then there were chronic patients, not likely to recover. The lecturer was not willing to admit that these would never come to be considered recoverable, for mental medicine had yet to get to the bottom of these cases; but as things were at present, some 15 or 20 per cent. of those admitted remained for life. The detached wards for these cases had nothing about them which was forbidding, but much, indeed, that was pleasing. For the safety of the public certain cases in a mental hospital had to have their liberty restricted; the only alternative would be an overwhelming number of nurses, and he did not think the end would justify the means. It was here, in what were known as the closed buildings, that the "asylum atmosphere" was to be found, but the signs of restriction, in the modern hospital, were never obtrusive. Patients suffering from epilepsy, again, had to be provided for separately, so that others need not witness their distressing state. Then there were people who, although *their mental illness* was protracted, were *very well behaved* and fond of employment; here there was no necessity for the regime of closed buildings; the patients resided in pleasant cottages, needing no lock and key, except at night. The very existence of these cottages and the liberty enjoyed by the patients there had been the means of encouraging patients of another class—patients who, though not turbulent or excited, were not very pleasant, or obedient, or amenable to persuasion, and had to be separately accommodated—to pay attention to themselves so that they, too, might leave the closed part and enjoy the greater freedom of their fellows. These well-behaved mental patients, for whom no restrictive regime was necessary, and who liked to employ themselves, amounted, usually, to some 16 per cent. of the residents, though it depended very much on the spirit of the institution; he had known institutions in which the figure had been as high as 25 per cent. Altogether, the conditions in a mental hospital were quite unlike the harsh and depressing picture sometimes painted. The lecturer had found that many who wrote and spoke criticizing mental hospital administration had to admit, on being challenged, that they had never visited a mental hospital in their lives.

Hospital Amenities.

Sir Hubert Bond briefly sketched the various departments of the hospital, the administrative block, and the equipment for medical treatment, which last was the same as that existing in the best general hospitals to-day, and included the *x*-ray department, the hydrotherapeutic department, verandah provision for open-air treatment, and so forth. The accommodation of the nurses was an important point. He remembered the day when every nurse in a mental hospital slept actually in the wards; that system was rapidly disappearing, and the nurses were now housed *in a detached home*. Liberal provision was also made for

the entertainment and recreation of the patients—a necessary and economical form of treatment. Another important point was the decoration of the wards with flowers and pictures, and the arrangement of the gardens and grounds. No small part of the business of the medical superintendent was concerned with the occupation of the patients. When he himself had charge of a mental hospital the residents themselves made the furniture, did the upholstery, wove the cloth for garments, made the boots, the mats, the brushes for the whole establishment, and did all the printing and bookbinding.

At the conclusion of the lecture a few questions were asked. In reply to a question as to what happened to a patient after discharge, Sir Hubert Bond said that London in this respect was fortunate in having a very efficient Mental After-care Association; he had never known this body let a case down. He wished to see every county with its own after-care association on the London model.

On a question as to out-patient clinics, he said that these did undoubtedly result in a decrease of hospital admissions. The best organized of these out-patient clinics was that at the Radcliffe Infirmary, Oxford, and it was significant that Oxford was the only mental hospital in the country where the population was decreasing.

VOLUNTARY HOSPITALS AND THE LOCAL GOVERNMENT BILL.

HARVEIAN LECTURE BY DR. E. GRAHAM LITTLE.

AT a meeting of the Harveian Society held at Paddington Town Hall on March 14th, Dr. E. GRAHAM LITTLE, M.P., delivered the Harveian Lecture, taking for his subject the voluntary hospitals and the Local Government Bill.

After describing the bill as the most important measure in its bearings on medical service that the present generation had seen, and sketching its main provisions, by this time familiar, Dr. Graham Little pointed out that it authorized and even encouraged county and county borough councils to provide hospitals and maternity homes, which would in all probability compete with the voluntary hospitals already in existence. Amendments proposed in both Houses of Parliament to provide machinery for securing co-operation between these new hospitals and the old voluntary hospitals had been refused by the Government, and he considered it true to say that there was no real check provided by the bill to prevent competition. Furthermore, the retention by the Minister of Health of complete control of all medical (as of other) officers under the scheme implied the wider extension of departmental autocracy over the profession, already experienced under the National Health Insurance Act. The Minister of Health had made no secret of his desire to extend the health services in such a way as to foreshadow their nationalization. The change in the relationship between the Exchequer and the local bodies also meant a further extension of the power of the Ministry. Block grants were to be substituted for the percentage grants hitherto made to local bodies, and the Minister reserved complete control over such grants, to vary or modify them as he willed.

Dr. Graham Little admitted the necessity for further institutional provision than the voluntary hospitals in their present state of development were able to supply, but he questioned the means proposed to that end. The reason why the voluntary hospitals had proved unable to meet the demands upon them was simply their popularity. The prestige of these hospitals explained why it was that patients were willing to wait for admission to them rather than seek immediate admission to existing Poor Law hospitals. There was no guarantee that patients would not still prefer to wait for admission to the voluntary hospitals. Government departments could not create prestige or personnel. The more logical and economical way of adjusting the difficulty of the empty beds at the Poor Law hospitals and the waiting lists at the voluntary hospitals would seem to be the provision of beds at those institutions where the demand [illegible] vision could be made at a sl[illegible] entailed by the staffing of new hos[illegible] special departments were already in [illegible] tary hospitals, and the extra expendi[illegible] more than the actual cost of providing [illegible] slight addition for the increase of medical [illegible] Ministry of Health was determined upon a [illegible] expensive and dubious experiment—that of e[illegible] the establishment of quite new hospitals—and no [illegible] whatever had been made to prevent competition [illegible] existing institutions.

During the last decade the voluntary hospitals ha[illegible] become largely self-supporting institutions, and a great [illegible] system of insurance for hospital service had developed, voluntary in character, but growing rapidly, and including quite new sections of the population. In these circumstances it was quite possible that the voluntary hospitals might elect to remain independent and continue as now, outside the orbit of the Ministry of Health, at any rate as regards management. They would probably continue to attract, thanks to the freedom and elasticity of the voluntary system, the services, medical and lay, of the best men and women of the time. Under modern conditions of the training of specialists it would be quite impossible to provide the new municipal hospitals with officers of the same status as those who staffed the voluntary hospitals without drawing upon the personnel of the latter.

Dr. Graham Little referred again to a scheme which he, with Mr. Walter Spencer, expounded in the *Times* fifteen months ago, and of which he spoke at the last Annual Representative Meeting. The scheme was, briefly, that in each area the voluntary hospital should take the lead, as its experience and prestige warranted, in the organizing of all the health services, and that a central advisory body should be constituted to guide and co-ordinate the services throughout the country, on which there should be representatives of the Ministry of Health and of the county councils, but with the representatives of the voluntary hospitals predominating. The nearer the new hospitals approached to the atmosphere and practice of the voluntary hospitals the more probable was their ultimate success in securing the confidence of patients, in maintaining economy and efficiency, and in gaining the enthusiastic co-operation of the medical profession.

ROYAL MEDICAL BENEVOLENT FUND.

SUBSCRIPTIONS are very urgently needed to enable the committee to meet the many calls for financial help which are made by those members of the medical profession, their widows, and dependants who are afflicted by poverty and want.

Each month, together with other applicants, there is more often than not a widow who comes for help, having been left destitute by the death of her husband; the amount the Fund is in a position to give is not adequate. Subscriptions and donations should be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W.1.

At the last meeting of the Case Committee of the Royal Medical Benevolent Fund forty-seven applications were considered, and forty-four grants were voted, amounting to £979 5s. The following is a summary of three cases:

Widow, aged 52, of M.R.C.S., L.R.C.P., *whose husband died in February*, 1929, has been left with £300; her annual income can only be £15. A few friends have clubbed together and have promised to give £60 yearly. The Fund voted £35.

Widow, aged 41, of M.R.C.S., L.R.C.P., whose husband died at the age of 56 in February, 1929. It is hoped that the practice will be sold for £1,750, the interest on which will be the widow's only income. There is a boy aged 9 to educate. The Fund voted a maintenance grant of £26; efforts will be made to find salaried employment for the widow, and help will be given for educating the boy.

Widow, aged 65, of L.R.C.P. and S. Was left destitute on the death of her husband; support of herself as companion to a lady, but has broken down in health, has had an operation, and is now a semi-invalid. Her annual income is £77. Fund voted £25.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

SATURDAY, MARCH 30TH, 1929.

FRACTURES OF THE ANKLE.

WE think it is a healthy sign that the treatment of fractures and the degree of success achieved in attempts to restore the injured parts *ad integrum* attract the increasing attention of surgeons. Particularly is this true as regards fractures of the lower ends of the bones of the leg and of the forearm involving the ankle-joint and wrist respectively. Any reduction in the efficiency of these joints means disaster for the working man and also a heavy charge on insurance funds. We recently commented on the good results obtained and statistics published by Messrs. Edwards and Clayton of the fracture department at King's College Hospital. The publication of this paper in our columns (January 12th, p. 61) was followed by one from Messrs. Grasby and Trick of Guy's Hospital (March 2nd, p. 391), and a fortnight ago Mr. Blundell Bankart contributed a valuable paper on the treatment of Colles's fracture (March 16th, p. 491), some letters in relation to which will be found at page 619. In our present issue (p. 585) we publish an article by Mr. Robert Ollerenshaw on the treatment of fractures involving the ankle-joint.

Such injuries as Pott's fracture have been frequently discussed, but there remains much to be desired in their routine treatment by the profession in general, and Mr. Ollerenshaw's contribution is welcome. As surgeon in charge of the orthopaedic department of the Salford Royal Hospital he has had good opportunities of acquiring experience, the results of which he communicated recently to the Manchester Surgical Society. Shortly, the result of an inquiry into 100 cases of ankle fracture of all kinds, including such severe injuries as fracture of both malleoli and of the astragalus, is that 89 returned to their *original* work, and that the average time of treatment of all the 100 cases was fourteen weeks, the extremes being eight weeks in the case of fracture of the external malleolus only and twenty-six weeks in that of marginal fracture. As these figures imply, the last-named type of fracture is the most disabling, while its existence may be overlooked and its treatment is difficult. The statistics of cure in the case of fracture of the external malleolus only are still better, for of 42 cases, 39, or more than 92 per cent., returned to their original work. As Mr. Ollerenshaw rightly points out, the statement "returned to work" is not a true indication of cure. A coal porter with a more or less disabled ankle might take up such work as driving a wagon, but if he returns to his original work of carrying two hundredweight of coal upon his back it is obvious that the cure is complete.

Radiographers of late have been able sometimes to hint to surgeons that they have not always appreciated the appearances on the *x*-ray plate or availed themselves thoroughly of the information it can give. Mr. Ollerenshaw is able to show that the report of the radiologist is not always infallible. In Fig. 1 of his paper he points out a gross subluxation of the astragalus from the tibio-fibular mortise in a radiogram on which the report was made of "no displacement." We do not wish to make much of such a case of carelessness, but mention it rather to enforce the teaching that in any cases of unilateral injury to a limb it should be an invariable rule that the sound member ought also to be *x*-rayed from an exactly corresponding point of view in order to provide a criterion of normality. Had this been done in the case in question it is not conceivable that the blunder could have been made. There seems no valid reason why, with proper teaching, every surgeon and every general practitioner who can obtain the help of *x* rays should not get a good result in the treatment of a Pott's fracture. The more severe and complicated injuries may call for special experience and skilled manipulation, and the correction of cases of malunion and old uncorrected displacement by open operation may well be left to surgeons with special experience. Such operations often call for the highest skill, the greatest experience, and the most well-balanced judgement. No routine rules for their performance can be laid down. Mr. Blundell Bankart, in his trenchant criticism of the treatment of Colles's fracture at a large teaching hospital, finds little on which to congratulate the surgeons in charge of these injuries at that school. Nevertheless it is a sign of grace that at such a school the importance of fractures of the wrist and their treatment is recognized in a way that would hardly have been probable before the war.

Such papers as this, and others to which we have referred, show that improvement has taken and is taking place, and we believe that the profession at large is aware of the need for improvement. When we compare Mr. Ollerenshaw's figures with those given by Clinton Dent little more than a score of years ago this encouraging fact is apparent. We believe and hope that the members of that admirable force the Metropolitan Police no longer have to leave the service because of Pott's fracture. All Mr. Ollerenshaw's "conclusions" are acceptable, but we would particularly lay stress on the last one—to the effect that "a fracture case, from the time of its arrival at hospital to the time of its discharge to work, should be under the supervision of one surgeon," and of one only.

THEORIES OF ENZYME ACTION.

SINCE the days of Pasteur problems of enzyme action have held the attention of biologists; indeed, though Pasteur himself was primarily interested in brewing and fermentation, he clearly realized the wide import of his observations. The years that have elapsed since his time have seen a tremendous accumulation of new facts concerning enzymes and their substrates, their source, and the conditions under which they act. To the pure organic chemist such observations must have proved a sore trial. To him cells and cell extracts often appeared simply as "messes"; yet they accomplished, at relatively low temperatures and close to the neutral point, reactions which he could himself bring about, if at all, only at high temperatures and with powerful reagents. It is not surprising that he was at first loath to admit the reality of the bio-phenomena described by the biologists and the bio-chemists. It is clear, however, that these enzyme actions underlie the activity of living cells. The common foodstuffs can be oxidized in the laboratory only by drastic means. The cells deal with them at 37° C. and at reactions close to neutrality; and even cells removed from the living body may retain the power of so doing. It is by these oxidations that the cells live and work. No one who believes in a greater future for medicine than that offered by empiricism and opportunism can afford to neglect such phenomena.

A review of the subject such as that given in Schoen's *Problem of Fermentation*[1] makes it plain that few of the aspects studied so far have much direct relationship to the immediate needs of medicine. The French and the Germans, who have been most active in the field, following in Pasteur's footsteps, have confined most of their attention to micro-organisms. Many of the data so obtained have found immediate practical application in industry. Apart from tanning and brewing, the development of the use of micro-organisms for commercial synthetic chemistry is as recent as it is extensive and striking. Remote from medicine, however, as such work appears to be, it is tempting to think that, could we but follow the clues correctly, the chemical behaviour of these useful and harmless organisms might throw light on the activities of their pathogenic relatives which command so much of our attention.

The study of the activities of mammalian tissue enzymes, difficult as it is, has proved and is proving fruitful. Following the lead of Hopkins and Fletcher, Meyerhof has partly unravelled the cycle of chemical changes underlying muscular activity; clearly, his thought has been greatly influenced by the similarities between carbohydrate degradation brought about by the yeast cell and that which occurs in muscular contraction. The work of Harden and Young on the importance of phosphates in alcoholic fermentation has its counterpart in the work of the Embden school on "lactacidogen." These points, again, are well discussed by Schoen. Wieland, Warburg, and Thunberg on the Continent, and Hopkins, Keilin, and Onslow in England, have built up a great structure of knowledge concerning oxidation systems, both plant and animal. If no comprehensive picture is yet possible there are at least many fragments waiting to be pieced together. But apart from increased knowledge of chemical mechanisms, has any helpful conception of the general nature of enzyme action yet emerged? Does, for example, Emil Fischer's "lock and key" hypothesis still hold the field? With the striking specificity of enzyme action in mind, Fischer postulated that an enzyme was a molecule having a special configuration that would fit the molecule of substrate just as a key fits a lock. Clearly, any given enzyme could thus fit but few substrates. Like Ehrlich's theories of immunity, the hypothesis was built around the facts, and as facts accumulated it became more and more unwieldy. It presupposed the enzyme to be a definite chemical entity; other facts make it certain that its molecule must be of colloidal dimensions; yet we have to picture for a single liver cell no fewer than fifty different sets of such molecules. Quastel states that in *B. coli* the number of enzymes dealing only with oxidations would have to be at least fifty-six. Moreover, many of these enzymes must be specially devised, as Hopkins first pointed out, to cope with materials which the cell could never meet unless it suffered the misfortune of falling into the hands of a biochemist.

It seems that the old theory, having done wonderful service in co-ordinating knowledge and stimulating new work, has had its day. Can we put anything in its place? Quastel and his collaborators, in a series of papers, a summary of which has recently appeared in the *Journal of Hygiene*,[2] have put forward a theory that seems to explain many of the facts, and to provide an excellent starting place for further work. It is interesting that they have once more turned to the micro-organism; to them, however, the micro-organism is not only a living entity: it is a convenient source of the enzyme systems which they wish to study. For purposes of their analysis, they have commonly used "resting" bacteria. These, they explain, are washed suspensions of bacteria which are used under such conditions that they are for the most part "non-proliferating" or "resting" during the time of experiment. They are by no means necessarily dead. Some of their most interesting results, however, have been obtained by using organisms which are, "bacteriologically," dead. On the basis of their researches Quastel and his collaborators conceive that an enzyme is not so much a specific chemical compound as the centre of a particular and sharply localized set of physico-chemical conditions. They suggest that at some colloidal surfaces centres exist where the arrangement of molecules may serve to set up powerful electric fields of force. Such conditions in the inorganic realm are perfectly familiar to the physicist. Molecules having a certain configuration will be attracted and held by the fields of force at these centres. Of the molecules so attracted or adsorbed a certain proportion, having again a definite structure, will be so affected that an electron shift will occur, and they will pass into a condition which enables them very readily to undergo chemical change. This process Quastel terms "activation." Only certain molecules within the range of the field can be adsorbed, and of these molecules only some will be activated. The process is to this extent specific, but the conception differs widely from that of specificity in Fischer's sense. On this basis it has been possible to predict what molecules will be activated by any given system, and to verify the prediction.

To certain orthodox bacteriologists the notion of working with "resting" or non-proliferating bacteria seems to have been a stumbling-block. To them, apparently, bacteria must be either living and proliferating, or dead and unworthy of notice. Such a view would definitely hinder the progress of our studies of the biochemical nature of bacteria and other organisms, for it is clearly of the greatest importance to understand in chemical terms what happens to an organism when it is exposed to different conditions, quite independently of whether it survives the exposure or not. If this were not so it would seem reasonable to object to most of the work done on yeast or on excised tissues, on the ground that these may not be capable of further normal function.

[1] *The Problem of Fermentation*. By M. Schoen. With an introduction by Professor A. Fernbach. A monograph of the Institut Pasteur translated by H. Lloyd Hind, B.Sc., F.I.C., and revised and enlarged by the author. London: Chapman and Hall, Ltd. 1928. (Roy. 8vo, pp. xii + 211. 21s. net.)

TUBERCULOSIS AMONG PRINTERS.

THE method of statistical analysis might be expected to supply data on which could be based an explanation of the comparatively high death rate from tuberculosis among members of the printing trades. Certainly there is very small measure of agreement about the explanations that have proceeded from other methods of inquiry. Lead poisoning of a slow, chronic, insidious form, producing not true plumbism but a lowering of resistance to infection, has been inculpated on the ground that in the printing trade lead poisoning and tuberculosis go hand-in-hand, both being higher in the occupations with greatest exposure to lead, and both falling as cleanliness and good ventilation increase. Alternatively, it has been held that the excessive incidence is due to cramped quarters, preference for working in an inadequately ventilated atmosphere, a

massive infections. Occasionally stress is laid on the presence in the atmosphere of dust and carbon monoxide created by the printing processes, and a lack of personal cleanliness and regular habits among the workers. These various explanations have this in common, that they invoke the influence of noxious factors in the printer's environment. On the other hand, it has been suggested that the cause may lie in the recruitment by the industry of persons of poor physique, a view which, however, finds no support in an American report by Hoffmann,[1] who concludes that there is no evidence "sufficiently pronounced to be suggestive of men of a decidedly inferior physique seeking employment in the printing trades." The problem is complicated by the fact that while the death rates from tuberculosis are in every age group higher among printers than among the general population of occupied males, the death rates from all causes, in almost every age group, are definitely lower. A statistical inquiry recently conducted by Dr. A. B. Hill[2] on behalf of the Industrial Fatigue Research Board into the incidence of sickness both from tuberculosis and from all other causes among the different occupational groups within the industry, while not explaining the relatively high tuberculosis rates among printers, brings out certain differences between the occupational groups which suggest lines along which a solution may eventually be reached. Medical examination of apprentices entering the trade should determine whether the high morbidity incidence of mortality among compositors aged 16 to 19 years, as compared with that among machine workers in the same age group, is due to the recruitment of weaklings in the one occupation and of a more physically select class in the other. Should it be found, in fact, that between these groups there is equality of physique on entry, some evidence of the effect of environmental factors would be obtained if the medical examination were made, not only on entry, but at intervals during the whole apprenticeship period. Detailed correlation of the conditions existing in specific printing houses, with their morbidity experience, would provide additional data to the same end. Dr. Hill finds that relative to their experience in later life the printers have high sickness and disablement rates in the first years of insurance, and that in this age group they occupy their most unfavourable position when compared with the general insured population. In later groups, on the other hand, they are at a distinct advantage, having throughout insured life a short-period incapacity rate about three-quarters of that for the insured population, and from the age group 35 to 39 onward a long-period incapacity rate only four-fifths of that suffered by other workers. Comparison of the occupational groups points to the conclusion that compositors begin, and perhaps end, their working life with an unfavourable morbidity experience, but that for all the intervening period they have a distinct advantage over others in the printing trade, their only rivals being the bookbinders and rulers. Excessive morbidity figures observed among the printers in the 16 to 19 age group are accounted for in large part by the high incidence of nearly all diseases at these ages among compositors, the latter, indeed, being almost entirely responsible for the pronounced tuberculosis rate in this age group. Phthisis is distinctly high for machine printers of ages 40 to 59, and for warehousemen of the age group 30 to 39; among compositors the liability to phthisis extends up to the age of 30, and reappears in the age period 60 to 69. It is possible that the long period of relative immunity enjoyed by compositors may be due to the operation of unfavourable environmental conditions which, while eliminating the weaker members by death, permits the survival of the more physically fit who possess or can acquire an immunity to tuberculosis. On the other hand, whatever may be the environment, if the occupation attracts an undue percentage of weaklings they would probably be eliminated from the trade, not necessarily because of the conditions of their work, but because they are unfit to retain their health and work under any conditions.

DOSAGE AND NOMENCLATURE OF DRY PREPARATIONS OF GLANDS.

GLANDULAR therapy is slowly but steadily increasing in importance as our knowledge increases concerning both the effects produced by the active principles, and also the methods by which these can be prepared in a stable form. One annoying source of confusion in glandular therapy is that there has been no generally recognized convention governing the measurement of the active substance contained in the preparations. Hence the strength of different preparations, as measured in terms of fresh gland, has varied considerably, and the confusion has been increased by the amounts of gland being expressed sometimes as weight of dried gland and sometimes as weight of fresh gland. For example, the term "1/2-grain tablet" applied to a preparation of thyroid may mean that the tablet contains 1/2 grain of dried thyroid, or it may mean that it contains the equivalent of 1/2 grain of fresh gland. This uncertainty sometimes results in patients receiving doses of gland very different in magnitude from what the prescriber intended, and it is a constant source of confusion when the results of glandular therapy reported by different authors are compared. The American Drug Manufacturers Association has now agreed upon a series of figures for the amount of fresh gland that a unit amount of preparation should represent, and also upon a standard nomenclature for these preparations. The following are examples of some of the agreed ratios and nomenclature:

Desiccated ovarian substance ...	1 : 6 of fresh ovarian gland.
Desiccated parathyroid substance	1 : 10 of fresh parathyroid gland.
Desiccated thyroid substance ...	1 : 5 of fresh thyroid gland.
Desiccated pituitary—	
Anterior lobe substance	1 : 5 of fresh pituitary anterior lobe.
Posterior lobe substance ...	1 : 6 of fresh pituitary posterior lobe.

If these conventions are generally adopted it will be a great convenience, for it will eliminate the unnecessary confusion that arises from the use of such terms as "thyroid extract," and also the uncertainty produced by such a term as "1/2 grain of thyroid."

LEPROSY IN THE BRITISH EMPIRE.

In its annual report for 1928 the committee of the British Empire Leprosy Relief Association reaffirms the belief that, if the plans which are now being advocated and put into operation in many parts of the Empire can be pushed forward with real determination, there is a possibility of abolishing this disease in many areas within the next thirty years or so. The work of the association is extending, and covers a variety of activities, some of which were described in our issue of June 23rd, 1928 (p. 1071). A new development is illustrated by the announcement that in Fiji nearly 1,000 trees which yield the oils used in the treatment of leprosy are now being grown from seed supplied by the association. It has been recognized that great advantages will accrue if the hydnocarpus oil can be obtained locally wherever it is used, and efforts of this kind are therefore being made in all parts of the Empire where leprosy work is being carried on. The anti-leprosy campaign in India continues to be pushed forward vigorously under the Indian Council of the Leprosy Relief Association, which,

at the instance of Lord Reading, when he was Viceroy, raised a fund of over £160,000 for this purpose. Branches of the association have been formed in many countries, and, during the year under review, the list of grants for enlarging the existing treatment centres and opening new ones shows a total of nearly £4,000. Regular supplies of the most effective drugs are being sent out to these centres, together with other necessary supplies. The association publishes a quarterly journal entitled *Leprosy Notes*, to which several references have been made in our columns.

B.C.G.

THE subject of pre-immunization of infants against tuberculosis by means of the Bacillus Calmette-Guérin continues to occupy the attention of the Académie de Médecine in Paris. Our readers may be reminded that Professor Calmette asserts that a virulent strain of bovine tubercle, attenuated by cultivation on a glycerinated bile medium, not only protects calves from infection with tuberculosis when injected under the skin, but also immunizes infants to the disease if administered by the mouth within ten days of birth. During 1928 a violent, if somewhat unconvincing, attack on Professor Calmette's assertions was carried on by Professor J. Lignières, a veterinary expert, references to which were made in these columns on May 26th (p. 909), June 23rd (p. 1077), and November 24th (p. 950). This attempt at vaccination against tuberculosis has been practised extensively in several parts of Europe, and in one of the Balkan countries the infants of whole communities have received doses of B.C.G. Nevertheless grave doubt has been cast upon Professor Calmette's use of statistics, notably by Professor Major Greenwood in the *British Medical Journal* of May 12th, 1928 (p. 793). At the session of the Académie de Médecine on December 18th last Professor Lignières returned to the charge with more orderly argument, designed to prove that the immunity conferred by B.C.G. is only relative and transitory. He contended also that the vaccination of healthy infants not exposed to the contagion of tuberculosis is not only unjustifiable, but may involve danger to the health of the infants. In the course of his communication Professor Lignières referred to recent experimental work with B.C.G. undertaken in Canada by Mr. E. A. Watson, in collaboration with Mr. C. W. McIntosh and Mr. H. Konst. These researches on B.C.G. and experimental vaccination against tuberculosis were conducted in the research laboratories of the Department of Agriculture, Hull, Quebec. They began shortly after the publication of Professor Calmette's work in 1924, and were directed first to the question of the pathogenicity of B.C.G. Of 134 guinea-pigs injected, 30 were found on death or slaughter to have tuberculous lesions, while in 12 there was extensive caseating generalized tuberculosis. As the authors were convinced that they could eliminate any question of spontaneous or naturally acquired tuberculosis in their guinea-pigs, and were equally confident that contamination of the B.C.G. cultures they used was impossible, they came to the conclusions, from their three and a half years' work, that B.C.G. had not been entirely deprived of virulence; that virulence was a *latent* property of B.C.G., requiring some unusual stimulus, and especially time to awaken it to activity; and that it was capable of causing in guinea-pigs, after a long period of infection and tolerance, a progressive and fatal tuberculosis, which was transferable from animal to animal in serial passage. The second part of the report of the Canadian investigators deals with experiments involving the vaccination of some seventeen calves with B.C.G. An attempt was made to reproduce conditions similar to those of the farm at Gruville, near Fécamp (Seine-Inférieure), where Professors Calmette and Guérin claimed great success for their method. But the Canadian animals were in a more favoured position in that they were drawn from tuberculosis-free herds. Yet all the seventeen animals—fourteen vaccinated and three used as controls—were found when killed to contain tuberculous lesions. The calves, after vaccination, were fed with the milk of tuberculous or suspected cows, as was done at Gruville; but it is noted that since 1927 Professors Calmette and Guérin have introduced an important modification of their methods, in that they now recommend that for thirty days after vaccination the animals should be fed only with boiled milk. The investigators are at present undertaking a series of experiments under the new conditions. It would seem, therefore, that the authors of the report, although anticipating severe criticisms of their experiments, are right in their view that B.C.G. vaccination is still in the experimental stage, and that its innocuousness and its efficiency are both open to question.

J. J. WATERSTON: A MAN BORN OUT OF HIS TIME

J. J. WATERSTON, born in Edinburgh in 1811 and educated in mathematics and physics under Sir John Leslie, at the age of 21 came up to London to train as a civil engineer. Having qualified, he sought for work that would enable him to follow his hobby—pure science. The post of naval instructor to the East India Company's cadets answered his purpose, "giving him leisure and no anxiety, care, or responsibility, and at the same time enabling him to lay up a little for old age." The rest of his life was devoted mainly to scientific thought. In his first serious adventure—namely, an attempt to express mental phenomena in terms of physical changes—he perceived that the excessive refinement of structural adaptations exhibited by living organisms must depend ultimately on molecular adaptations. To molecules, therefore, he turned his attention, since he felt that, in whatever way the phenomena of nature were examined, molecularity was the grand terminus to which all investigations tended. Thus he was led to the study of molecular physics, and in particular to the physics of gases; and in this branch he exhibited a penetration which marks him out as one of the greatest thinkers of the nineteenth century. He discovered that the physical laws common to all gases and vapours could be brought under one broad generalization on the assumption that a gas consists of molecules travelling with enormous rapidity in every possible direction. A carefully written paper, in which this dynamical theory of gases and of heat and temperature was formulated with great precision and clearness, was sent in to the Royal Society in the year 1845—and rejected. The two referees appointed to examine it pronounced it unworthy of publication, one of them expressing the opinion that it was "nothing but nonsense, unfit even for reading before the Society." In itself the incident may be considered trivial, but its practical effect was permanently to eclipse Waterston's splendid generalization. By the rules of the Society publication of the paper elsewhere was prohibited, and although Waterston made some attempts to draw attention to the subject, his efforts were without effect. The discovery was made afresh by other men some fifteen years later, and before the end of the century the dynamical theory had become a commonplace in ordinary textbooks. The incident has a pleasant sequel. A few years after Waterston's death Lord Rayleigh discovered the now celebrated paper in the archives of the Royal Society, and published it in the *Philosophical Transactions* (1892), with a generous appreciation of Waterston's work; and recently Professor J. S. Haldane has edited the collected works,[1] prefaced by an interesting

[1] *The Collected Scientific Papers of John James Waterston*. Edited, with a biography, by J. S. Haldane, M.D., LL.D., F.R.S. Edinburgh and London: Oliver and Boyd. 1928. (Med. 8vo, pp. lxvii + 709; illustrated. 25s. net.)

biography of Waterston, whom he actually ranks highest in the brilliant group of physicists turned out in the early part of the last century by the Scottish universities, including such men as Brewster, Forbes, Thomas Graham, Andrews, Rankine, Kelvin, Clerk Maxwell, Tait, and Balfour Stewart.

TENDENCIES OF MEDICAL EDUCATION IN AMERICA.

THE transition from individualism and *laissez-faire* to communal interference and even control, effected in this country during the middle of the nineteenth century, has had its counterpart in the United States during the last fifty years. As in England so in America, this evolution has not been achieved without considerable changes in social theory—changes, moreover, which have not been confined merely to the domains of politics and economics, but have invaded that synthesis of ideas and beliefs and aspirations collectively known as the spirit of the age. When economic life was dominated by *laissez-faire* so were other institutions, so even was ethics. The gradual supersession of individualism in industry, the revolution which began with factory legislation and moved irrevocably to trusts and rationalization, has been accompanied by a transformation not only in political theory, but by a corresponding change in the structure of nearly all social institutions. In America the most striking changes have been effected in medical education. William Low Bryan, president of Indiana University, writing in the *Journal of the Association of American Medical Colleges*, states that in the past fifty years America has seen the substitution of extreme licence in medical education by the other extreme of social control. As recently as twenty-five years ago America swarmed with medical schools, each autonomous and determining its own course of study and standard of qualification. Many of these schools were fraudulent and unable to give proper training for medical practice. Then, under the inspiration of the American Medical Association, came the passing of *laissez-faire*; schools were inspected with relentless thoroughness, black lists were published, and the weaker schools perished by the score. Within an astonishingly short time so extreme a revolution has been wrought in medical education that there are now signs of a reaction towards the old individualism. In other educational institutions, in the colleges of arts and sciences, this reaction is already an accomplished fact; daring educational experiments are being made, and here and there students are immune from strict prescription in their course of study. In Indiana the non-medical student is free of all rules except that he must not shoot a professor; Mr. Bryan does not state if this rule is rigidly enforced. Significant of the present-day tendency—the tendency perhaps to blend what is best in social organization with a healthy individualism—is Mr. Bryan's peroration. "Across the path of every man," he says, "are the traffic cop, the health officer, and the rest of the police. What is infinitely more important, across the path of the youth are the schools and licensing boards which allow him or forbid him to make his living at his chosen profession. . . . Our task, and if necessary our fight, is to keep the school and all standardizing agencies in continuous living adaptation to the needs of man."

BRITISH JOURNAL OF UROLOGY.

A WELCOME and important venture in medical journalism is the publication, by Messrs. Constable and Co. Ltd., of the first issue of the *British Journal of Urology*,[1] a new quarterly periodical, edited by Mr. Frank Kidd, M.Ch., F.R.C.S., and Mr. H. P. Winsbury White, F.R.C.S., with the assistance of an editorial committee of British urologists. This is the second periodical in English devoted to urology, the first being the *Journal of Urology*, founded in America ten years ago. In a letter which appeared in our columns on March 2nd (p. 421) announcing the forthcoming publication of the new journal, it was pointed out that, although there has been an active British section taking part in the congresses of the International Society of Urology, and the council of the Royal Society of Medicine has thought fit to establish the subject of urology as a separate section, and not as a subsection of surgery—thereby showing that urology was held to be entitled to differentiation as a separate subject for study—"there is nowadays such abundance of special work being done that can only find a voice if it can be given the additional outlet of a journal specially devoted to the subject." The editors of the *British Journal of Urology* hope that not only will the new publication unite in closer harmony and lend added prestige to the work of the ever-increasing number of urological workers in the British Empire, but that it will serve as a link between urologists in England and their colleagues in other countries. In each number, for the help of visitors, will be published a list of the chief British urological clinics, and the editors hope further, by the publication of articles from American writers, to fulfil the great responsibility that rests on all scientific workers to strive for comity among the nations and an age of peace. The present issue contains several original articles, records of interesting cases, biochemical notes, urological hints for practitioners, abstracts from current literature, and an index to that literature conceived on modern lines. A great deal of the material is of interest as much to the general practitioner as to the specialist in urology.

INFLUENZA.

IN the week ending March 16th there was a substantial decrease in the mortality attributed to influenza, as well as in the incidence of notified pneumonia. In the great towns the deaths assigned to influenza fell from 2,127 to 1,552, and in England and Wales the number of notifications of primary pneumonia decreased from 5,818 to 4,897. Some Midland cities—for example, Nottingham and Derby—and some cities of Yorkshire—for example, Bradford—had more deaths from influenza than in the previous week, but in most the maximum was reached earlier. The West Midland area, where both notification and death rates were highest in the previous week, still suffered greatly. The rate for deaths from influenza (based on towns only) has fallen in the West Midlands from 234 per million to 171, and the notification rate of pneumonia from 302.7 to 263.1 (by a slip of the pen these rates were erroneously stated last week to be per 100,000 instead of per million). In the south-western area and in Wales the notification rates of pneumonia were still increasing last week, but were on a relatively low level. On the whole, although no doubt mortality will continue to be abnormally great for some weeks, there is sufficient evidence to justify the belief that a general decline has now set in. The recrudescence has been the most serious since the great pandemic, and has taken a heavy toll at ages beyond middle life.

THE PRINCE OF WALES, President of King Edward's Hospital Fund for London, has appointed Lord Dawson of Penn, G.C.V.O., to be a member of the General Council of the Fund.

SIR BERKELEY MOYNIHAN, Bt., upon whom the King has conferred the dignity of a Baron of the United Kingdom, has adopted the style and title of Baron Moynihan of Leeds in the County of York.

DERMATOLOGY AND GENERAL MEDICINE.

THIRD LETTSOMIAN LECTURE BY DR. H. W. BARBER.

IN his third and concluding Lettsomian Lecture[1] delivered to the Medical Society of London on March 22nd, Dr. H. WORDSWORTH BARBER said that in previous lectures he had emphasized the close relationship existing between the skin and the sympathetic nervous system and ductless glands, and he proposed in this lecture to carry the consideration forward, in the first place, into that group of disorders to which Freeman had given the name of "toxic idiopathies," and, in the second place, into a trio of closely related cutaneous conditions—namely, alopecia areata, vitiligo, and scleroderma.

"Toxic Idiopathies."

In speaking of these he called attention to the regrettable tendency which still existed of referring to them as if they were diseases *sui generis*. They included a number of cutaneous, subcutaneous, respiratory, gastro-intestinal, and nervous conditions—for example, in the cutaneous group, urticaria, true infantile eczema, certain forms of eczema occurring after infancy, and some forms of pruritus and prurigo; in the respiratory group, hay fever; in the gastro-intestinal group, certain forms of vomiting and diarrhoea; in the nervous group, migraine. He adopted Freeman's term "toxic idiopathies" because it conveniently indicated their toxic origin and implied idiosyncrasy. By idiosyncrasy he meant that certain persons had an inborn tendency to develop sensitiveness to one or more foreign substances, though idiosyncrasy was a relative term of widely varying incidence. Dr. Barber gave several illustrations of such sensitiveness, and among other observations mentioned that all those who constantly handled salts of nickel sooner or later suffered from nickel dermatitis, showing that the liability to become sensitized by contact with certain substances was found in so great a number of persons that it could not be attributed to individual idiosyncrasy. On the other hand, only a relatively small proportion of those who handled primula became sensitized, and there was often a familial idiosyncrasy towards this plant.

Various observations went to show that the toxic idiopathies, although often familial and hereditary, might nevertheless be regarded as allergic in nature. There was a type of person whose life-history might be said to be "one damned idiopathy after another," though such extreme cases were relatively uncommon. One particular symptom might be traced through several generations, but more often the affected members of the same family manifested different symptoms. Moreover, there was every gradation, from these rare cases of hypersensitiveness to various antigens, with multiple symptoms, down to the cases which showed one symptom only. Probably what was inherited was a disordered balance in the make-up of the endocrine autonomic system on which this tendency depended. A perfectly normal person, with no inherited predisposition, might under stress of an acute or chronic infection or a severe emotional shock develop symptoms of such disturbance with, for the first time in his life, one or more toxic idiopathies. The lecturer had seen asthma, for example, after acute infections or shock. He thought the toxic idiopathies might justifiably be considered as allergic reactions, and the cutaneous manifestations compared with eruptions such as the tuberculides and trichophytides.

Factors Predisposing to the Sensitized State.

Among the toxic idiopathies some cases were met with—for example, hay fever due to a particular pollen, or urticaria from some specific food substance—which were constants, the skin giving a specific reaction, and the whole phenomena being capable of reduction to a relatively simple physiological experiment; but in many other cases no such specific sensitiveness could be found. It was known that the urticarial wheal was provoked by a histamine-like substance or by histamine itself in the skin. Such a response might follow in certain persons merely from stroking the skin; in others from contact of an antigen with sensitized skin cells. Presumably it was a local defensive mechanism. But how was so-called psychogenic urticaria to be explained? One patient consulted him for genuine attacks of urticaria occurring whenever he was confronted with an important business appointment or the prospect of meeting strangers socially. Was it to be supposed that in emotion or anxiety there was a liberation of histamine? In practically all the toxic idiopathies the anxiety state alone might provoke the paroxysms.

The known factors predisposing to the manifestation of the sensitized state were: (1) sensitizing with foreign substances; (2) peripheral irritation; (3) psychical stimuli. The presence of a so-called reflex source of irritation might be of great importance, and was often forgotten. In asthma it was well known that a nasal abnormality might be the provoking cause of the attacks; similarly an overloaded stomach or exposure to strong sunlight might excite the asthmatic paroxysm. Eyestrain, a painful tooth, a misplaced uterus, might provoke disproportionate symptoms of sympathetic disturbance. Those who suffered from the toxic idiopathies, as Freeman pointed out, fell into the hands of different specialists in turn. These patients more than others provided a handle to the accusation against the specialists, and demanded from their consultants a range of knowledge wider than was usually to be expected. In addition to the three factors just mentioned there was a fourth, namely, the metabolic factor, and the lecturer had something to say on the investigations into cyclical changes and on the metabolic restoration following an alteration of environment.

Alopecia Areata, Vitiligo, and Scleroderma.

Dr. Barber turned next to the trio of related conditions already mentioned—alopecia areata, vitiligo, and scleroderma. The literature regarding these conditions, he said, was enormous, but the involvement of the autonomic nervous system was apparent from the experimental and clinical observations. He contented himself with some comparisons between the three conditions and with a brief treatment of each in turn. All three, for example, might occur in a localized and in a generalized form. He discussed the changes which constituted the life-history of a patch of alopecia areata, and particularly emphasized the redistribution of the pigment whereby the part near the root of the hair became depigmented, and, secondly, the atrophy of the hair, which did not occur after parasitic infections such as ringworm. The real significance of the "exclamation mark" hairs in alopecia areata was that, apart from this condition, they were met with, so far as he knew, only on depilation by *x* rays and on the internal administration of thallium acetate. In the etiology of alopecia areata there was the following significant fact: that two at least of the factors which he had mentioned as predisposing to the toxic idiopathies came into play—namely, peripheral irritation and psychical stimuli. There was general agreement as to the importance of the psychical factor in many patients with alopecia areata, and numerous cases had been recorded in which a definite shock preceded its onset. One of his patients had three separate attacks, each one immediately after the death of a relative.

In vitiligo the same predisposing factors were found clinically—namely, peripheral irritation and psychical stimuli. One feature of vitiligo of great interest was its association with pigmented moles, but the discussion of the full significance of this would involve the origin of naevi. He quoted cases, one following a nervous breakdown, which supported the idea of the sympathetic nerve origin of vitiligo. He also referred in the same way, but more briefly, to scleroderma, mentioning its frequent association with thyroid disorders and its occurrence both in Graves's disease and in myxœdema.

In conclusion, Dr. Barber said that he had tried to emphasize the importance of the skin as a vital organ both in health and disease. The appreciation of this importance was gradually gaining ground, but ignorance of the most elementary principles of the etiology and pathology of the skin was widespread. It seemed to him that the student might profitably spend more time in studying the changes

[1] The first and second lectures were reported in the *British Medical Journal* of March 2nd (p. 412) and March 16th (p. 513) respectively.

in the skin and mucous membrane indicative of metabolic changes or the beginnings of disease, and be excused the study of much less relevant matter.

Dr. PARKES WEBER, in proposing a vote of thanks to the lecturer, said that general practitioners were conspicuous, in England at any rate, for their carelessness with regard to the dermatoses, though they had great responsibility thrown upon them in the certification of cases. Dr. HALDIN-DAVIS, in seconding, said that dermatology had been honoured in the choice which the society had made for its Lettsomian lecturer, who had ably demonstrated, what was sometimes forgotten by the physician, and even by the dermatologist himself, that dermatology was a branch of general medicine.

England and Wales.

Royal Sanitary Institute Dinner.

THE annual dinner of the Royal Sanitary Institute was held at the Hotel Metropole on March 21st. The Duke of Northumberland, K.G., presided over a large and distinguished company, which included representatives of Government departments, the services, and medical bodies. Sir John Rose Bradford, P.R.C.P., in submitting the toast of "The Public Health," said that the present was a time, if rightly used, of great promise to public health and to the future of medicine. The Local Government Bill, then in its final stages in the House of Lords, was of supreme importance from that point of view. With regard to the future of the voluntary hospitals he himself had no fear. He did not believe that the British public would tolerate the disappearance of such institutions. While it was true that if the voluntary hospitals disappeared expenditure would be increased by millions, the monetary loss would be small compared with the other losses involved. It must always be kept in mind that the standard of medical treatment, the advance of medical knowledge, and the training of doctors and nurses were mainly due to the voluntary hospitals. The experience and the spirit of the voluntary hospitals must be not only preserved but extended to, and incorporated with, the other institutions with which the present legislation primarily dealt. Sir Arthur Robinson, Secretary of the Ministry of Health, said that he knew the Minister would be ready to adopt as his own every word that Sir John Rose Bradford had said with regard to the voluntary hospitals. He went on to say, after a brief review of recent progress in public health, that, while it was often necessary to dilute the ideal with the practical, the Ministry in the course of years, and very largely owing to the inspiring lead of the present Minister, had come appreciably nearer to one of its ideals with the passing of the Local Government Bill, which touched not only public health, but nearly every element in local government administration. That measure gave to the Ministry, the local authorities, voluntary associations, and the medical profession magnificent opportunities. Actually as it stood it was a great public measure, and potentially it was a still greater one. He could promise that, so far as the Ministry was concerned, there would be a continuance in the well-tried way of partnership with the local authorities and their staffs, and with the medical profession. The toast of "The Royal Sanitary Institute" was proposed by Sir Ewen Maclean, President of the British Medical Association. After touching on the value and scope of the Institute, he went on to show that, in spite of a certain impression which might have been gained from Sir John Rose Bradford's remarks, the financial factor had to be taken seriously into consideration in connexion with the voluntary hospital system. From certain investigations he had carried out he found that for £50,000 put into a voluntary hospital, value to the extent of £1,500,000 per year was returned to the community; at a moderate computation he valued the services of the honorary staff at £350,000 annually. Sir Ewen Maclean added that there was one man who had to be taken into account in all schemes of reconstruction touching the public health—namely, the general practitioner. Any scheme which was so foolishly devised as not to utilize the general practitioner's knowledge and experience was doomed from the first to a severe handicap. He hoped the general practitioner side of the question would be taken into account. The Duke of Northumberland, in responding, referred to the great progress in sanitary science which had taken place during the history of the Institute. The great duty to which the Institute was committed was the education of the citizens in the laws of sanitation. As the science of sanitation improved, multitudes were kept alive who in former times would have been carried off by disease. This in itself raised new problems which would have to be solved before many years had elapsed, and yet another problem would arise with the increasing restrictions which the improvement in sanitation imposed upon the liberty of the subject. But the Institute could not be wrong in pursuing its educative work. Professor Bostock Hill, chairman of council of the Institute, proposed the health of "The Guests," to which Sir Humphry Rolleston, Bt., and Sir Holburt Waring briefly replied.

Extension of University College Hospital.

Prince George presided over the annual meeting of the Corporation of University College Hospital on March 21st, when Sir Herbert Samuelson, chairman of the general committee and treasurer, presented the reports and accounts of the hospital. Sir Herbert said that the past year marked the first stage in the extension scheme initiated in 1922; with the completion of the reconstruction of the main hospital buildings the full complement of 529 beds became available. The Rockefeller Foundation had given a sum of approximately £31,000 to build a new preliminary training school for nurses, and it was hoped that the building would be completed within the next twelve months. The number of in-patients treated during 1928 was 7,753, as against 6,580 in 1927; the out-patients' attendance figure was 258,142, comparing with 247,786 in the preceding year. The hospital was still seriously handicapped by having insufficient supplies of radium at its disposal; although the generous gift of £50,000 to the King's Fund by Sir Otto Beit for the purchase of radium for loan to hospitals would temporarily relieve the situation, the demand for further supplies would soon become pressing. It was hoped that Sir Otto Beit's fine example would evoke other benefactions of a similar nature. Sir Herbert Samuelson referred to the fact that negotiations were in progress between the London County Council and representatives of the voluntary hospitals in London regarding the public health services and the provision of more adequate hospital accommodation; he expressed the hope that the voluntary hospitals, while maintaining unimpaired their traditional heritage, would be assigned a definite and responsible place in the public health service of the country. The income of the hospital for the year was £110,664, an advance of £21,527 on that of the preceding year. The increase reflected the result of a special appeal inaugurated by the Duke of Bedford to clear off the debt of £30,000. The expenditure for 1928 was £100,654, which was larger by £10,005 than the sum spent in the previous year. In order to meet the estimated expenditure of £108,000 for 1929, when the full resources of the hospital would be available, it would be necessary to raise at least £30,000 from voluntary subscriptions and donations.

The Minister of Health at the Royal Free Hospital.

The Minister of Health attended the annual court of governors of the Royal Free Hospital, London, on March 19th. In a reference to the future of voluntary hospitals under new legislation he said that he thought the apprehensions of many were unfounded. It had been feared that the support of municipal hospitals by the rates would mean the end of the voluntary system. If such a result did follow it would be very unfortunate for the ratepayer, because he would have to take on his shoulders a burden hitherto borne by private generosity. But the fact was that these municipal hospitals could not be carried on effectively without the good will and co-operation of the voluntary hospitals. He had recently inserted in the Local Government Bill a clause which made it a statutory duty for local authorities, before considering how to dispose of the hospital accommodation with which they had

to deal, to consult with the bodies in their area representative of the voluntary hospitals and their staffs. The changes made by the bill, so far from injuring voluntary hospitals, would establish them in a position of security such as they had never yet enjoyed; they would be an indispensable feature of the institutional system in their areas. Mr. Chamberlain then turned to the Royal Free Hospital, which, he said, was a century-old example of the value of the voluntary system. It was remarkable also in that it trained only women doctors; he congratulated the hospital on having the names of three of its members in the recent Honours List. The successful invasion by women of almost every sphere of professional and public life was one of the features of the present age. At the same time the callings which had always been, and always would be, predominantly feminine had not suffered. There was no service of which the country had more reason to be proud than its nursing service. At the end of 1928 there were 64,000 nurses on the register for England and Wales, and in the previous year nearly 15,000 had given notice of their intention to practise as midwives. Both in general nursing and midwifery the standard had been continuously raised, so that to-day the qualified nurse was not merely a servant of the doctor, but his intelligent co-operator and partner. It was just seventy years since the name of the first woman doctor—Elizabeth Blackwell—appeared on the *Register*. According to the census of 1921 there were 1,200 women doctors, and since then between 2,500 and 3,000 women had entered the profession. There were also women dentists, pharmacists, veterinary surgeons, and sanitary inspectors; in law, surveying, architecture, accountancy, and in analytical and research chemistry, many women were engaged. In his own department, added Mr. Chamberlain, he was very conscious of this influx. Last year the local authorities were making use of 2,280 health visitors, all of them women, and in addition 340 visitors were employed by voluntary agencies in connexion with infant welfare centres. In the civil service it was no secret that women were entering the administrative grades in open competition; the first woman to succeed was to-day an officer of the Ministry of Health. All this was a noteworthy change in our social system. Mr. Chamberlain looked forward with satisfaction to the growing assistance of women in local administration. Last year no fewer than ten women had been elected mayors. In the Local Government Bill it was provided that where co-option took place on the committees and subcommittees of local bodies some of the co-opted members must be women. He believed that many ladies who, shrinking from a contested election, began by being co-opted, would have their interest so keenly enlisted that if the way of co-option were no longer open they would endeavour to enter as elected members. Prejudice against the progress of women was disappearing, and their co-operation entailed an enrichment of the life of the community.

Northampton General Hospital.

The annual report of the Northampton General Hospital for the year ended July 31st, 1928, will serve to remind its readers of the fact that, while the position of the voluntary hospitals, as a whole, has improved materially since the critical years after the war, there are many institutions which are still faced with crippling financial difficulties. The managers have been able to reduce the average costs per patient, and the ordinary income was slightly higher; in all departments, however, the work of the hospital has increased and the total expenditure has advanced somewhat. Consequently there was a deficit on the current account of over £3,881, and £5,650 has been transferred from legacy account. It may be added that a similar procedure was necessary in the previous year, when the board, faced with an accumulated deficit on working of almost £7,600, took £7,910 from legacy account. The financial reserves of the hospital have consequently been depleted, with a progressive loss in investment income. An appeal is being made for additional annual contributions, amounting to about £5,000 a year, to enable the hospital to balance its accounts in the future, and for donations to wipe out the existing deficit and provide for necessary expenditure. Attached to the report of the hospital is that of the Northamptonshire Hospital Week Committee, which, to present one of the more gratifying features of hospital finance, illustrates the growing importance of organized effort in the collection of moneys for the hospitals. An analysis of the amounts raised by this agency compares the results achieved in the eight years before the war with those of the past eight years by this body and the Northampton Hospital and Convalescent Fund. The average for each year in the pre-war period was £2,020, and for each year in the more recent period £11,148; in the earlier period such contributions equalled 17 per cent. of the hospital's expenditure, and in the later period 30 per cent. of its expenditure. A special effort is being made to complete the Hospital Week Committee's Jubilee Fund, which is to be used to provide a new operating theatre block.

Health and Cleanliness Council.

The Health and Cleanliness Council, which exists to diffuse information about the advantages of cleanliness, and to this end co-operates with public and educational bodies, held its third annual meeting at the Hotel Cecil on March 20th. Dr. G. F. Buchan, the president of the council, at a luncheon which preceded the business meeting, said that the number of representatives of voluntary agencies and local authorities present this year was 188, 32 more than on the last occasion. He explained that the council, at its annual meeting, determined the policy, and an advisory board existed to carry it out. During the year the council had assisted 156 health weeks, co-operating with the medical officers of health and with other organizations in arranging for exhibitions and demonstrations. Prizes were given for essays by school children, and essays from 1,750 schools were submitted for the award of the judges. Various publications to a total of five million copies had been distributed, and a book on health and cleanliness, for the use of teachers in schools, had been accepted in the areas of 145 local education authorities. Some education authorities were allowing the systematic use of their hoardings for the council's effective posters. A cinematograph van was another useful means of propaganda, and since its installation the demand upon its services had been greater than could be met. As a crowning glory the council was given a place in the Lord Mayor's Show, and the exhibit was effective enough to turn even the thoughts of Gog and Magog to soap and water. Dr. Buchan added that the aim of the council was at something more than mere aesthetic cleanliness—namely, at a cleanliness which had its roots in biology. Dr. F. E. Fremantle, M.P., also gave an address in which he spoke of the need for inculcating the health habit. He thought it was sometimes forgotten in the modern "push" for hygiene that, after all, the essential thing was not good housing nor the observance of the rules of sanitation, greatly important as these were, but a healthy spirit in the mind and habit of the people. Given such a spirit, they could, on occasion, disregard any of the rules of health, forego the customary precautions, break the usual regime, sure that the true spirit and understanding would never permit undue transgression. The important thing was the spirit, not the schedule, and he commended the council because it was endeavouring not to put forward a meticulous code of health, but rather to evoke the spirit and desire for health and cleanliness from which all else would follow. After the business meeting those present had the opportunity of seeing the exploits of the latest film star, "Giro the germ."

Coroners' Inquests in London.

The number of deaths reported to the London coroners in 1928 was 8,516, an increase of 838 upon the figure for 1927. Of these deaths, 2,653 took place in mental hospitals and other institutions. An inquest was deemed necessary in 4,173 cases, and 76 per cent. of the inquests, including hospital cases, necessitated *post-mortem* examinations. A verdict of murder was returned in 18 cases, of manslaughter in 2, and of suicide in 571, the last figure representing a decrease of 40 on the previous year. Seven inquests were held in connexion with executions. Deaths from want of attention at birth increased from 27 to 44.

In all, 2,137 persons met their death by accident, as against 1,916 in 1927. There were 55 deaths by drowning. A verdict of "death from natural causes" was returned in 1,129 cases, and there were 14 verdicts of "cause of death unknown." The inquests on newly born children decreased from 108 to 104; there were three verdicts of murder of the newly born, and in 37 cases it was decided that the child was stillborn. Excessive drinking accounted for 30 deaths, the same number as the previous year.

Scotland.

THE KING has appointed Dr. William Macrae Taylor, late surgeon major, 1st Lowland Brigade, R.F.A.(T.A.), to be Surgeon Apothecary to His Majesty's Household at the Palace of Holyroodhouse, in succession to Colonel David James Graham, O.B.E., R.A.M.C.(T.A.), deceased.

Training of Deaf and Dumb Children in Edinburgh.

An interesting survey of the activities of the Edinburgh Royal Institution for the Education of Deaf and Dumb Children was presented to the directors at the annual meeting by Dr. Kerr and Mr. B. P. Jones, late superintendent of the deaf and blind education under the London County Council. The institution consists of two departments: the school proper with between 90 and 100 children, and the Strathern House Nursery School for 30 children, aged 3 to 8. Each child was examined individually, and its capacity for speech and for understanding others was tested by various standards. As a result it was estimated that one in five will leave school understanding and able to be understood by strangers, that a third of the whole will be able to be understood and to work in familiar surroundings, while the remainder will experience more or less difficulty. An unusually high percentage (68) of totally deaf cases, and a similarly high proportion of congenital cases, were noted: the explanation was offered that the baby school is attracting numbers of obviously deaf children, and that others with defective hearing are being cared for elsewhere, or possibly neglected. The risk of partially deaf children becoming dumb for want of immediate care, and the value of early education of the deaf, are stressed and it is noted with satisfaction that the number of children admitted to this institution below the age of 7 years is very large. Among the causes of deafness it is noted that meningitis is incriminated in 17 out of 45 pupils over the age of 9, while among the 60 below this age no meningitis case appears. Meningitis being a rare cause of deafness in this country the suggestion is made that these cases are attributable to the war. The success of a nursery school for the deaf is considered by the examiners to have been demonstrated, and suggestions are made for obtaining improved results in the case of the older children: one proposal is that the possibility of combining the present separate efforts should be explored, and a single educational institution be established for training deaf children in Edinburgh.

Glasgow Royal Hospital for Sick Children.

The annual report of the Royal Hospital for Sick Children, Glasgow, shows that during the past year the number of patients treated in the wards of the hospital numbered 6,492, while the attendances of out-patients at the dispensary connected with the hospital numbered 90,585. At the country branch of the hospital at Drumchapel 502 children were treated. The ordinary income for 1928 was £29,543, and the expenditure £39,989. The deficit in ordinary income was made up from extraordinary income with a surplus of £1,950, and as the ordinary income had shown an increase of £2,300 over that of the previous year, the deficit was slightly less than before. The directors make a special appeal for a fund of £20,000, of which the income would be spent in providing the necessary facilities for research into the causes and prevention of diseases of infancy and childhood, which is urgently required at the present time and which they feel should not be a charge upon the ordinary funds of the hospital.

Preventive Medicine in Teaching.

Dr. J. Parlane Kinloch, Chief Medical Officer of the Department of Health for Scotland, delivered the closing address for the winter session to the students of the Anderson College of Medicine, Glasgow, on March 16th, and took as his subject "Preventive medicine and the medical curriculum." Dr. Kinloch said that in recent years medicine was being studied and taught from a new standpoint, and that teachers in the several departments of medical study were tending more and more to treat their subjects from a preventive point of view. It was one of the aims of the legislature, as well as being desired among the people of this country, that there should be an adequate health service for the whole community. This would involve training of the people in personal hygiene, supervision of maternal and child life, as well as of school life and industrial life, and of the environment in which they lived, together with the comprehensive prevention and treatment of infectious and non-infectious disease. Certain axioms of preventive medicine should be constantly perceptible to the student in all aspects of his work. These included heredity, which determined the inherent constitution of the body; the control of environment, especially in regard to ventilation, water supplies, and insect control; the ways of increasing general resistance to disease by nutrition, open air and sunlight, adequate exercise and rest, etc.; the methods of active protection, which involved the whole range of immunizing processes; and lastly, the epidemic constitution—that is, the factors determining epidemic prevalence. A continued improvement in medical education would certainly lead to an improvement in the medical service, but the conception of prevention must first dominate the entire system of medical teaching. In order to have an adequate medical service it was necessary that the training and work of the general medical practitioner and of the statutory medical officer should be co-ordinated, so that the general practitioner should regain his position of family doctor, fully responsible for watching over the family health and for preventing disease, and employing for that purpose the official machinery provided by local authorities. It might be asked how the medical student was to find time within his five years of training for these further practical studies. His suggestion was that much of the older pharmacology, the older pathology in so far as it related to degenerative processes, and a great deal of the fascinating study of forensic medicine might be omitted from the ordinary medical course, and be reserved for those wishing to specialize after graduation.

Ireland.

School Medical Inspection in Dublin.

IN the course of a lecture for nurses on school medical inspection Dr. Kerry Reddin recalled that in 1879 a definite inspection of school children was established in Paris, and shortly after in Sweden and Belgium. In 1891 similar action was taken by England, which was followed quickly by America and Egypt. Saorstat Eireann had definitely adopted the scheme. The objects of school medical inspection were fourfold: (1) for statistical purposes, to show the physical condition of the child and to establish facts in connexion with the alleged defective physique of children; (2) to benefit the individual child; (3) to conduct propaganda about teeth, digestion, and personal hygiene; and (4) to improve the sanitary condition of the schools in which the children worked in regard to ventilation, light, heating, overcrowding, lavatory and urinal accommodation, washing and drinking facilities, and to supply adequate playgrounds. Medical inspection was provided (1) on admission to school, (2) at the age of 8, and (3) at the age of 12. Dr. Reddin said that up to the end of December they had inspected approximately 12,000 children. Of these 7,000 had one or more defects; 5,000 of these required treatment immediately, and 2,000 were under observation; 2,243 were suffering from tonsillar affections, of whom 507 required treatment and the

remainder were under observation; 1,433 suffered from defective vision, and of these 1,000 required treatment immediately, and 433 were under observation. These figures did not include cases of squint, of which there were nearly 500. There were also 630 cases of external eye affection. Of skin diseases, including ringworm, there were 442 cases, 300 of which required urgent treatment, and 142 were under observation. There were 227 cases of ear disease, of which 132 required treatment, and the remainder were under observation.

Public Health in County Limerick.

At the last meeting of the Limerick County Council a letter was read from the Department of Local Government and Public Health relative to the question of the appointment of a medical officer of health for the county. The department expressed the view that the appointment of such an officer should be considered in conjunction with the county sanitary services on the lines presented by the Local Government Act, 1925. That Act contemplated that the general direction of the public health activities of each county should be placed in charge of a county medical officer of health, whose function had been clearly described in detail. Among other matters of pressing importance might be mentioned eradication of diphtheria and enteric fever cases, the prevention and correction of crippledom, the reduction of infant mortality, which, in the case of co. Limerick, had maintained an exceptionally high incidence for an area comprising no urban districts, and the protection of women against the special dangers associated with childbirth. A school medical service controlled by a county medical officer of health would quickly follow, and provide early treatment for potential cripples, while after-care could be attended to by voluntary organizations. In the county of Limerick the maternity death rate among women from puerperal sepsis stood at an average in advance of any other county in the Saorstat, being, in 1924, 3.65; in 1925, 3.18; in 1926, 4.17; and in 1927, 3.29. From these figures it would be seen that in the county of Limerick there was unmistakable need for organized supervision over maternity practice. The chairman pointed out that every progressive country had such a scheme in operation, and other counties in the Saorstat were already working such a scheme. After some discussion it was decided to adjourn the matter for a fortnight.

Correspondence.

COLLES'S FRACTURES.

SIR,—My friend Mr. Bankart, in an interesting note on Colles's fracture (March 16th, p. 491), states that he never, or hardly ever, sees a case of Colles's fracture which is properly reduced, and he adds:

"The reason for these uniformly bad results is that the method of reduction almost universally employed—namely, that advocated by Sir Robert Jones—is entirely inadequate in the hands of the majority of those who have to treat these cases. . . . It may be that the powerful hands of Sir Robert Jones (and some others) can reduce a Colles's fracture in any manner that he chooses; but . . . the method which he advocates is quite inadequate in the hands of the great majority."

Mr. Bankart pays me an undeserved tribute when he speaks of my "strong hands." My hands, alas! can no longer be classified as strong, but I have no more difficulty now in reducing a Colles's fracture than in the days of my youth. Strength is not an important asset, but the method of its application is.

The principle which underlies my very simple procedure is extension of the radius, pronation of the lower fragment, and supination of the upper. The grip I employ involves *direct* pressure on the lower end of the radius, and disimpaction and reduction are effected by a combined movement.

I have seen many surgeons attempting to reduce a Colles's fracture by the "Jones method" in a hopelessly inadequate fashion. They hold the hand, put traction on the wrist-joint, and pronate. The strength of Samson would be helpless to effect reduction in this way.

The method described by Mr. Bankart, where the arm is placed upon a wedge block, is very like my own as far as the act of reduction is concerned, but apparently no traction is used and preliminary disimpaction is not aimed at. This must involve greater force and crushing of the lower fragment—certainly more force than I ever use. It is surely hazardous to apply the whole of one's body weight—even occasionally—upon a fractured end with the palmar aspect of the wrist over a wedge. There must be some risk of injury to tendons and nerves if this method be followed. I know Mr. Bankart's work so well that in his own careful hands I could predict that his patient would be immune from damage, but what of others? Is it wise or safe?

No, strength is not an important factor. My friends who have watched me reduce this fracture know how little I depend on force. Indeed, in many cases I use no anaesthetic, for the manipulation is rapid, and after the momentary pain of reduction little further complaint is made.

I agree that once reduction is complete the question of type of splint is of no great importance.—I am, etc.,

Liverpool, March 18th. ROBERT JONES.

SIR,—In your issue of March 16th Mr. Bankart made some very interesting observations on the treatment of Colles's fracture. I heartily agree with his general conclusions, but think that the method he advocates of reducing deformity as a routine with the aid of a wedge is open to criticism. There is no doubt that the injury in question is the result of great force, and that impaction of the bone fragments is generally correspondingly firm. Brute force will, no doubt, break through this impaction and approximately reduce the deformity, but there must surely be a risk of serious damage to the nerves and tendons lying between the bone end and the wedge when this method is employed. I have observed evidence often enough of partial involvement of the median nerve, due either to the primary injury or to subsequent manipulation. Damage to tendons or their sheaths always results from the primary injury. Any increase of this caused by the process of reduction must certainly delay return of full function.

It appears to me that in order to replace the lower end of the radius the ideal procedure is to disimpact and then to manipulate the fragment into position. If this procedure is effectual there is much less risk of damage to soft parts. One must admit that there are cases in which manipulation by hand fails to effect full reduction, even when the attempt is promptly carried out. I think then that open reduction through a dorsal incision is justifiable. It is a simple procedure, and it can be carried out with a minimum of trauma to the surrounding structures.

I very heartily agree with Mr. Bankart in his condemnation of the use of the Carr's splint for holding the Colles's fracture. I think there is now general agreement that fixation after reduction is best secured by a dorsal splint with the wrist in a flexed position.—I am, etc.,

London, W.1, March 19th. C. MAX PAGE.

SIR,—In your issue of March 9th (p. 477) Mr. Cochrane drew attention to non-reduction of the forward luxation of the head of the ulna as the real cause of so many bad results in the treatment of Colles's fracture. For this reason we have reviewed the *x*-ray plates in our series of Colles's fractures before reduction, and could find only one particularly severe case in which a true luxation definitely existed.

In addition, some hundreds of *x*-ray plates had been examined previously, and we have no notes of the form of luxation to which Mr. Cochrane refers. It would appear, therefore, that Cotton's forward luxation of the head of the ulna must be uncommon as a cause of unsatisfactory results, our experience being precisely that of Edwards and Clayton.

Mr. Bankart will forgive us if we politely but firmly disagree with the statement in his article of March 16th (p. 492) that "the position of supination is irksome to the patient and not really necessary." As we remarked, the

position is quite comfortable in spite of the forearm being fully supinated, and we believe the position to be necessary because some Colles's fractures have shown a tendency to reproduce the displacement after reduction.

In answer to the last question raised by Mr. Bankart we would add that, through the kindness of Mr. Slesinger, surgeon in charge of the fracture department of Guy's Hospital, Colles's fractures, with others, are reduced by house-officers—a possible explanation for the unsatisfactory results we have found. And also that Mr. Slesinger kindly permitted us to try our own methods of treatment.—We are, etc.,

E. DUDLEY GRASBY,
SCOTT-RUSSELL TRICK.

Tunbridge Wells, March 18th.

THE THERAPEUTIC VALUE OF ULTRA-VIOLET LIGHT.

SIR,—Having read the remarks on artificial light treatment in the report of the Medical Research Council, 1927–28, may I call the attention of your readers to certain statements therein contained?

On page 14 the following lines appear: "*Since the invisible rays of ultra-violet 'light' were found to hold the nutritive properties of sunlight*" (italics mine), "it was natural to suspect that artificial lamps, rich in ultra-violet rays, might be an effective substitute for the missing sunshine in our cities." The first statement in this sentence is incorrect. We know that ultra-violet rays convert ergosterol into vitamin D, and therefore produce the physiological phenomena caused by that product, but this is far from proving that they "hold the nutritive properties of sunlight." Such an assumption is jumping to conclusions, and almost certainly very wide of the mark.

Later (page 15), the report states that "exactly the same effects for good or evil follow inflammation of the skin blood vessels inflicted by heat or by other irritants than light. There is no present reason to know that artificial light can do more in this way than a mustard plaster, which is indefinitely [*sic*] cheaper." The only interpretation to be put upon this statement is that the investigators selected by the Medical Research Council have been inflaming the skin of babies by a dosage of ultra-violet light sufficient to produce this effect. Could any experienced clinician expect to obtain by such means the beneficial effect of properly applied treatment by artificial light? Does the Council really mean, moreover, that a child can be cured of rickets by the application of a mustard plaster? If so, can it quote any case in which such a result has been obtained? We may surely ask it to support its statement by scientific evidence.

On page 14 it says, "No evidence could be found of any gain in weight, of lessened anaemia, or of better resistance to infective illnesses in the treated group as compared with a similar group of untreated children." This statement will cause little surprise.

There is one more sentence that cannot be passed over without comment: "It would seem also to be the special duty of hospitals and schools or other clinics expending large sums of public money upon artificial light to use part of the expenditure to demonstrate by properly controlled trials their justification for spending more." All the great hospitals in London, not to mention the provinces, have expended such sums upon the establishment of departments for giving treatment by artificial light, because this form of treatment has been more than justified by the results obtained, and the sentence is a direct reflection upon the distinguished medical men who are responsible for their administration and to the executive bodies concerned in this considered expenditure.—I am, etc.,

G. MURRAY LEVICK.

London, W.1, March 19th.

SIR,—With reference to the recent report of the Medical Research Council it might be of interest to recapitulate the conclusions I arrived at as the result of work at Queen Mary's Hospital, Carshalton. They were as follows:

1. The light bath gives pleasure to the vast majority of patients and has no dangerous after-effects.
2. Patients with superficial tuberculous ulcers, rickets, and debility do well, but these cases are easily treated without the use of light. The local application of the rays is of value in the treatment of lupus, but the general light bath has little effect.
3. The course of tuberculosis of the spine, hip, or knee, with or without sinuses, is apparently not influenced in any way by the action of light.
4. The treatment gives no protection against the spread of infection.
5. Pigmentation of the skin has little, if any, clinical significance, and absence of pigmentation is no contraindication to light treatment.
6. Light treatment has no definite influence on the physical or mental development of the normal or subnormal child.

The report was published in full in the Annual Report of the Metropolitan Asylums Board, 1925–26, and was referred to in the *British Medical Journal* of August 28th, 1926 (p. 399). Although various modifications of the technique have been tried, the results obtained since 1926 have not led me to alter, to any great extent, my opinions on the value of actinotherapy. The great benefit that is derived from ultra-violet light is a transient feeling of well-being; this, coupled with the healthy appearance it gives the patients, has undoubtedly a beneficial influence, and for this reason only I consider the administration of ultra-violet light justifiable.—I am, etc.,

N. GRAY HILL, *M.C.*, M.B., B.S.Lond.

Queen Mary's Hospital for Children,
Carshalton, Surrey, March 19th.

VACCINATION IN THE LIGHT OF RECENT EXPERIENCE.

SIR,—Dr. F. A. Belam, in the *Journal* of March 16th (p. 524), raises the important practical question of the relationship of "severe" small-pox to the "mild" variety (alastrim), with which we are now so familiar. He concludes that the two (types) "do not breed true to type, but true to disease, of which there is one."

I would suggest to Dr. Belam that a better view of the situation is as follows. We are not dealing with two different "types" of small-pox (the word "type" has merely a clinical significance), but with two distinct varieties. In each variety one may meet both mild and severe clinical types; consequently mere clinical mildness or severity is of no pathognomonic significance in any given case. For the same reason, to call one variety "severe small-pox" and the other variety "mild small-pox" is futile and only adds to the confusion. A far better nomenclature is "variola major" and "variola minor," as first suggested by R. W. Jameson.

The essential and all-important difference (although there are others) between variola major and variola minor is that whilst the one propagates a serious, fatal, and permanently disfiguring affection, the other propagates an affection which (for practical purposes) is non-fatal, non-disfiguring, and clinically trivial. The fact that a small proportion of the cases of variola minor (say, 5 per cent.) can be classed as clinically severe, with a profuse eruption, and that there is a possibility that occasionally, at the extremes of life or in debilitated subjects, the affection may even prove fatal, does not affect the truth of this as a general proposition.

As to the question whether we can rely upon variola minor to maintain its present mild type, or whether it may not revert to the characteristics of variola major, the answer is that although it has now been recognized in this country for over a decade, it has as yet shown no tendency (judging by its case mortality) to increase in severity, or to approximate to variola major in virulence. Any reports to the contrary can be accounted for by local fluctuations such as we find with any epidemic disease. More important is the fact, as testified by that astute observer Dr. C. V. Chapin of Providence, that in U.S.A. there is also no evidence of any reversion. Moreover, there is reason to believe that in certain countries variola minor, under the names of alastrim, amaas, Kaffir-pox, etc., has existed from time immemorial, yet has continued to breed true.

The answer, then, to the question whether we are dealing with one disease or with two, is that there is one disease, small-pox, with two distinct varieties. These two varieties are doubtless very closely related. They have a very

similar relationship to vaccinia, and there is little doubt that they confer mutual immunity against each other. The position is analogous to that of typhoid fever and paratyphoid, and there is a good deal to be said for the names suggested by R. P. Garrow—namely, "*small-pox*" and "para-small-pox."

In view of all this I suggest that in the interest of statistical accuracy it is eminently desirable that the Ministry of Health should now recognize that we are dealing with two entities and authorize distinctive names. At the same time they could enact that both varieties were notifiable and that both could be covered, in any case of doubt, by the one word "small-pox." So long as cases of variola major are included in the same column with cases of variola minor any figures as to case mortality are clearly valueless.—I am, etc.,

Leicester, March 16th. C. KILLICK MILLARD.

THE INTRACUTANEOUS TUBERCULIN TEST.

SIR,—Now that Professor Lyle Cummins has entered into details, I am more than ever convinced that my criticism is sound, and I fear the finding of the investigators adds nothing to our knowledge, and may mislead some who are not *fully conversant with the nature and* meaning of the interesting and illuminating manifestations of allergy, brought to our notice by means of various methods of injecting tuberculin.

Professor Cummins describes the lesion caused by intracutaneous injections of tuberculin as "a raised plaque of oedema, usually surrounded by a blush, etc." The lesion which I can produce at will in a tuberculous subject is certainly not "a plaque of oedema," and a plaque of oedema in no way resembles a "cocarde" (Mantoux). The lesion of my making is a red, raised, indurated, painful, tender area of inflammation, resembling a Pirquet lesion. It is not an oedematous condition, but an inflammatory formation caused by the reaction of sensitized tissue to the specific toxin of the tubercle bacillus. It is a form of allergic reaction, the histology of which has been described and explained in all its wonderful detail by the late Professor K. E. Ranke. Moreover, this allergic manifestation cannot be adequately described on the third day. It may persist for many weeks. I shall therefore be greatly surprised if "this most important result so far gained from our Welsh investigation" does not prove to be worthless. Long ago I said this of Professor Dreyer's work on his "diaplytes," as soon as his work was published, and I was right. I say the same of Professor Cummins's paradoxical views upon the reaction of tuberculin.

But Professor Cummins goes beyond his text, and ventures to make this statement in his reply: "so far as adults in this country are concerned, a positive tuberculin reaction has no diagnostic significance whatever."

The *post-mortem* records of E. France, Mikulicz, Mettetal, and Binswanger show that a positive tuberculin reaction in the hands of experts has the most profound diagnostic significance. Professor Cummins can hardly impeach the evidence of various experts derived from direct *post-mortem* examinations.

There is also clinical evidence, indirect and direct. In my Parkes Weber prize essay, published in 1912, I have tabulated over 120 cases in which a wrong diagnosis was given till I tested with doses of tuberculin. For years I have been investigating certain lesions of the eye, both in children and adults, the cause of which was undetermined until I used tuberculin for diagnosis. Most of these patients came from ophthalmic surgeons. The lesions were chronic conjunctivitis, scleritis, episcleritis, and irido-cyclitis. Till tuberculin was used for testing tuberculosis was not suspected. What is true of lesions in the eye or skin or throat, which we can see, is equally true of tuberculous lesions hidden from sight or too small to give any evidence of their existence until tuberculin tests are properly conducted and logically interpreted by a trained expert.

I trust that medical men will pay no heed to unwise condemnation of the indispensable diagnostic agent discovered by Koch, which should be exploited consistently and zealously on behalf of suffering humanity. If Professor Cummins would pay me a visit I would gladly show him the history of numberless cases, in which test doses of tuberculin have established beyond doubt the etiological factor in many obscure forms of disease, which defied diagnosis by any other means. The advantage of early diagnosis largely depends upon this scientific test. Surely it is a golden truth in tuberculosis that, when diagnosis is easy, treatment is difficult, and when diagnosis is difficult, treatment is easy.—I am, etc.,

London, W.1, March 16th. W. CAMAC WILKINSON.

ESTIMATION OF HEPATIC EFFICIENCY.

SIR,—With regard to the article on estimation of hepatic efficiency published in the *Journal* of March 2nd (p. 395) it may be of interest to note that at the Royal Mineral Water Hospital, Bath, there was carried out for two of the honorary physicians (Dr. Gordon Watson and Dr. Lindsay), on seventy consecutive cases admitted to their wards, Roch's test for the antitoxic function of the liver, as described in *Physiological Principles in Treatment*, by W. Langdon-Brown (fifth edition, p. 165).

This test was made because focal sepsis, so often assigned as the cause of rheumatoid arthritis, seemed an insufficient explanation; so many people have marked focal sepsis and yet do not get rheumatoid arthritis that one suspected it was not the focal sepsis, but some flaw in the antitoxic powers of the bodily metabolism which might be at fault. The liver is the great detoxicating organ of the body; was the liver the offender in these cases? It was decided to test its antitoxic function. The results are quoted below.

Rheumatoid arthritis:		Neuritis:	
Roch's test ++	in 60%	Roch's test ++	in 35%
" " +	in 16%	" " +	in 16%
" " −	in 24%	" " −	in 49%
Fibrositis:		Sciatica:	
Roch's test ++	in 70%	Roch's test ++	in 33%
" " +	in 6%	" " +	in 11%
" " −	in 24%	" " −	in 56%
Osteo-arthritis:		Subacute rheumatic infection:	
Roch's test ++	in 15%	Roch's test +	in 50%
" " +	in 32%	" " −	in 50%
" " −	in 53%		

++ = a strong purple colour given.
+ = a definite change of colour.
− = no change of colour.

It should be noted that this test is for the antitoxic function only, and these notes are sent, not in vindication of Roch's test, but impartially to show the reactions which occurred in these seventy rheumatic cases.

The results were published in the *Proceedings* of a conference on rheumatic diseases held at Bath in May, 1928, and I am making this communication with the kind permission of the two honorary physicians on whose cases the tests were made.—I am, etc.,

LEO DELICATI,
Resident Medical Officer, Royal Mineral Water Hospital, Bath.
March 5th.

THE HISTORY OF CINCHONA.

SIR,—In the paper on the history and lore of cinchona read in the Section of History of Medicine at the Annual Meeting of the British Medical Association at Cardiff and reported in the *Journal* of December 29th, 1928 (p. 1183), Mr. C. J. S. Thompson refers to the "picturesque story" of the fortuitous discovery of the virtues of cinchona bark by an Indian who drank of water into which a cinchona tree had fallen. Mr. Thompson remarks that the st which was not recorded until the eighteenth centu without foundation. It does not, however, appear generally known that a play based upon this story produced by Montigny, the director of the Gymna the Ambigu-Comique Theatre in Paris in the th My authority is Vandam's *An Englishman in Paris* (man and Hall, 1892), vol. i, p. 226. I r to

a summary of the play as given in a note in that interesting book of reminiscences.

"The play . . . was called "Amazampo; or the Discovery of Quinine." The scene was laid in Peru in 1636. Amazampo, the chief of a Peruvian tribe, is in love with Maïda, who on her part is in love with the son of the viceroy. Amazampo is heart-broken, and is stricken down with fever. In his despair and partial delirium he tries to poison himself, and drinks the water of a pool in which several trunks of a tree called *Kina*, reported poisonous, have been lying for years. He feels the effect almost immediately, but not the effect he expected. He recovers and takes advantage of his regained health to forget his love passion, and to be avenged on the oppressors of his country, many of whom are dying of fever. Lima becomes a huge cemetery. . . . Amazampo saves the life of the wife of the viceroy by compelling her to drink the bark-impregnated liquor.

I have never had an opportunity of seeing a copy of the original play, but am sending you this note, which I trust may be of interest to your readers.—I am, etc.,

Kenya Colony, Jan. 27th. JAMES H. SEQUEIRA.

DIET AND APPENDICITIS.

SIR,—In his very interesting address published on January 5th (p. 6) Mr. Zachary Cope puts forward the suggestion that "a predisposition to appendicitis would be lessened by (1) preventing constipation, (2) minimizing the amount of meat eaten, and (3) increasing the amount of food containing cellulose." In support of this may I be permitted to bring forward the following observations?

In my work here I am dealing almost entirely with native people of the Bantu race, and it is a fact of my own experience, and also in that of others, that appendicitis is exceedingly uncommon in them. In the light of the above suggestions it is interesting to observe the habits and customs of these natives as regards bowel evacuation and food.

Constipation.—The natives regard themselves as being constipated if they do not go to stool at least twice a day. Quite commonly they go out three or four times in the course of a day. In this connexion it is to be noted that in their squatting attitude while at stool they employ the pressure effect of the muscles of the abdominal wall to the best advantage. The comfortable water closets of civilization do much to minimize the valuable aid of these muscles.

Meat.—While it is true that the natives are exceedingly fond of meat, it is equally true that they very seldom have it in ordinary circumstances. They are not regular meat-eaters, and the total quantity eaten by the average native in the course of a year is very much less than that consumed by the average European.

Cellulose-containing Food.—The staple article of food among all classes of natives is "mealies" (or maize). They have mealie meal porridge every morning; stamped mealies in the middle of the day; and again the porridge at night. Variety is afforded by the addition of brown beans at midday, and by the occasional use of "kaffir-corn" in place of mealie meal. Even their bread is made from mealie meal; and all this food is very rich in cellulose. In Britain we should give it only to horses. Thus there are in the life of the Bantu people three important factors which, theoretically at least, militate against the onset of appendicitis: (1) frequent and regular evacuation of the bowels, (2) the absence of much meat in the diet, and (3) the presence of abundant cellulose in the everyday food. These people do not suffer from appendicitis, and, moreover, they are not afflicted with gall-bladder affections; as Mr. Cope reminds us, cholecystitis and appendicitis are frequently found together.

While it would appear, then, that the simple diet of these native people serves to protect them from two of the serious diseases of the digestive system, it must also be pointed out that it is by no means a good all-round diet. It is deficient in vitamin quality, and the health of the natives suffers in consequence of his deficiency. That, however, is another question altogether, and does not affect the truth of what I set out to show.—I am, etc.,

R. L. PATERSON, M.B., Ch.B.

Buchanan Medical Mission, South Africa, Feb. 5th.

MINOR ORTHOPAEDICS IN GENERAL PRACTICE.

SIR,—In reference to Dr. R. A. Murray Scott's letter in the *Journal* of March 16th (p. 524) it may be of interest to him to know that nearly thirty years ago I purchased boots, of the shape he desires, at Holden Brothers, Harewood Gate, Oxford Street, W. Their business has been recently transferred to Messrs. T. Holland and Son, 48, South Audley Street, W.

I have recommended boots and shoes of anatomically correct shape to a number of patients for many years. Women, particularly, are difficult to persuade, and many will suffer agonies rather than wear a shoe which they allege is ugly and not "stylish"; on the other hand, not a few, after experience, have been thankful for the advice.

An important matter also, especially for children, is the shape of the sock or stocking. Much of this make of footwear is pointed at the toes and will not allow sufficient expansion for the big toe to take up a straight position, but shops dealing in "hygienic" footwear can supply these articles with a straight "inside" line.—I am, etc.,

W. W. SHRUBSHALL, L.R.C.P.Ed., D.P.H.Lond.

Burgess Hill, March 18th.

CYCLICAL VOMITING.

SIR,—The apparent error which Dr. H. C. Cameron (March 23rd, p. 573) points out in your account of my paper on the chronic dyspepsias of childhood at the Medical Society of London (March 16th, p. 502) was the unfortunate result of compression in your otherwise excellent summary of my remarks. The actual words I used were:

"The frequency of this form of latent acidosis has been much emphasized by Dr. Cameron, and Dr. Osman has stated that 30 per cent. of hospital children suffer from cyclical vomiting."

—I am, etc.,

London, W.1, March 23rd. REGINALD MILLER.

Obituary.

DR. JOHN LAIRD, who died in February at the age of 84, after only three hours' illness, received his medical education in Dublin, where he obtained the diploma L.R.C.S.I. in 1865, and the L.R.C.P.I. and L.M. three years later. For fifty years he conducted a large practice in Sligo, and was subsequently granted a pension by the Sligo board of guardians in acknowledgement of the valuable services he rendered. He contributed many papers to medical periodicals, and wrote a book on tuberculosis, which reached a second edition. He was highly appreciated by his colleagues, and was on one occasion invited to be president of the Irish Medical Association, but declined, being of a retiring disposition. He was buried in Mount Jerome Cemetery, Dublin, on February 25th.

DR. JAMES WILSON, who died on February 9th at his residence in Claughton, at the age of 87, was educated at King Edward's School, Birmingham. When 22 years old he went to America and acted as surgeon to the Northern Forces throughout the whole of the campaign in the late American Civil War, receiving subsequently the thanks of the President and Congress of the United States. He then returned to England, and engaged in medical study at the Universities of Aberdeen and London, obtaining the diploma M.R.C.S.Eng. in 1861, the L.S.A. in 1862, and graduating M.D., C.M.Aberd. in 1875. For a few years he was physician and laryngologist to the Worcester General Infirmary, but a breakdown in health necessitated his undertaking a sea trip to Australia. He later commenced practice in Liverpool, where he specialized in diseases of the throat, nose, and ear. After thirty-six years, however, a second breakdown in health compelled him to limit himself to consultation work. He wrote numerous articles and books, chiefly relating to diseases of the nose and nasopharynx. He was for some time physician for diseases of the throat and nose to the Liverpool Clerks' Association, and medical referee to the National Sanatorium for Consumption at Bournemouth; he had also held

a commission as surgeon in the Royal Navy. He was one of the pioneers of cautery treatment for turbinal hypertrophy, and achieved a distinguished reputation as a specialist in diseases of the nose, throat, and ear. Eight years ago he retired finally, and went to live in Birkenhead. He was twice married, and is survived by his second wife.

Dr. ARNOLD WILLIAM MONTFORT AUDEN of Birch House, Leigh, Lancashire, who died at his residence, after a week's illness, on March 6th, at the age of 65, had been in general practice in Leigh for thirty-four years. The eldest son of the late Rev. W. Auden of Church Broughton, Derbyshire, Arnold Auden was educated at Shrewsbury School and at Clare College, Cambridge, where he graduated B.A. in 1885. He was a man of fine physique and an oarsman of considerable ability, rowing in the school crew at Shrewsbury and for his college at Cambridge. In other directions also he was a distinguished athlete, winning, when at Shrewsbury, the senior steeplechase and the quarter-mile, among other events. After a period as schoolmaster he decided to enter the medical profession, graduating M.B., C.M. at Edinburgh University in 1895. While at Edinburgh he served in the Queen's Rifle Volunteer Brigade. In his practice he was much beloved by all his patients; he was especially considerate to the poor, and a generous subscriber to numerous charities. He was a keen freemason, and held the appointment of medical officer to several of the local collieries. He will be greatly missed in the neighbourhood, and his funeral was an impressive tribute to the respect in which he was held. He was a member of the British Medical Association.

Dr. EDMUND LEE, who died on March 20th, in his eighty-fourth year, was a well-known and highly respected figure in North Manchester medical circles. He was educated in Manchester, and having obtained the diplomas of L.R.C.P. in 1871 and M.R.C.S. in 1873, he engaged in private practice, the whole of his active professional life being spent in Collyhurst, a densely populated industrial district, where his genial and kindly manner and sound attainments attracted a large clientele. In spite of the physical exertions incidental to this class of practice, he maintained the keenest possible interest in the progress of scientific medicine. His leisure hours were largely devoted to keeping himself abreast of such advances as seemed likely to be of practical service to his patients. He was a man of wide reading, and this, coupled with his daily contact with suffering and poverty, gave him an unusually broad, sane, and sympathetic outlook on life. For some years he was chairman of the North Manchester Medical Union. He was hardly ever absent from the meetings, feeling social intercourse with professional colleagues to be an important factor in promoting understanding and *esprit de corps*. He had a record of some fifty years of quiet, unassuming, useful work, and a reputation for fair and neighbourly dealing. At the end of a long life he leaves behind a very pleasant memory. Two of his sons are in practice in Manchester.

Dr. ALEXANDER GRANVILLE, who died in London on March 23rd after a long illness, was born in Egypt in 1874, and received his medical education at St. Bartholomew's Hospital. He obtained the diplomas of M.R.C.S., L.R.C.P. in 1894, and held the offices of house-surgeon and house-physician at the West London Hospital and senior assistant anaesthetist at St. Bartholomew's Hospital. He served in the South African war during 1899–1901, and was awarded the Queen's medal with three clasps. He subsequently joined the Egyptian Government Service, where he held several important posts, including those of inspector of the Public Health Department, medical officer of health for Cairo, director of the Municipal Section of the Ministry of Interior, Cairo, director-general of the Alexandria Municipality, Egypt, and president of the International Quarantine Board of Egypt. He received the honours of C.M.G. and C.B.E. in 1916 and 1920 respectively, and was created a Pasha by King Fuad in 1922 in recognition of his services on the Labour Dispute Conciliation Board of Egypt. He was a Knight of the Order of St. John of Jerusalem, Grand Officer of the Order of Ismail, and had been the recipient of honours from France, Italy, Greece, and Belgium.

The following well-known foreign medical men have recently died: Dr. VAN BOECKEL, principal public health inspector in Belgium; Dr. LÉOPOLD BAUMEL, honorary professor of the Montpellier Medical Faculty, aged 75; Dr. BARATTE, formerly director of the health service of the Dardanelles Expeditionary Force and Commander of the Legion of Honour; Dr. GIUSEPPE TAGNINI, a Bologna neurologist who has given his name to the oculo-cardiac reflex, aged 62; Dr. PIETRO GIACOSA, director of the Institute of Materia Medica and Pharmacology at Turin, aged 75; Dr. J. VON KRIES, emeritus professor of physiology at Freiburg, aged 76; and Dr. ALEXANDER MAXIMOV, an histologist and haematologist of Chicago.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Local Government Bill.

Third Reading in the House of Lords.

IN the House of Lords, on March 21st, Lord ONSLOW formally moved the third reading of the Local Government Bill.

Lord DE LA WARR said that peers belonging to the Labour party must continue their opposition to the Bill. It would put some social services, notably the health services, on a block grant system based on a three-year period and thereafter for five-year periods. There was no guarantee in the bill that at the end of those periods new money would be forthcoming from the Exchequer to meet the new demands of the localities. Local authorities would be less free to provide new services.

The LORD CHANCELLOR said the Government believed that in the bill it had effected improvements in the efficiency of social services.

The motion to read the bill a third time was carried by 70 to 11, and the House went on to make final amendments to it.

Clause 2, dealing with the functions of Poor Law authorities in respect of infant life protection and vaccination, was amended to allow councils to acquire land in pursuance of such purposes.

The House then renewed consideration of points left open at the end of the report stage concerning Clause 13. This clause, inserted to meet representations by Lord Dawson of Penn, ran:

13. The council of every county and county borough shall, before making provision for hospital accommodation in discharge of the functions transferred to them under this part of this Act, consult with such committee or other body as they consider to represent both the governing bodies and the medical and surgical staffs of the voluntary hospitals providing services in or for the benefit of the county or county borough.

On the motion of Lord ONSLOW the House agreed to substitute "before making provision" for "when making provision," and to leave out the word "with" from the phrase "consult with such committee." Lord Onslow further moved to add at the end of the clause words providing that the consultation should be "as to the accommodation to be provided and as to the purposes for which it is to be used." He said these words were introduced to meet the wishes of Lord Dawson as far as possible, and he understood that Lord Dawson would accept it. The Government wished to meet in every way it could the Lords who represented hospitals.

Lord DAWSON OF PENN thanked Lord Onslow for trying to meet the view held by himself and his friends. The clause did not do all they asked, but certainly went further than the earlier offer of consultation on "accommodation" only. The clause would bring the people who knew into contact with those who had to administer. It did not go as far as it would be necessary to go in administrative matters. That the mass of the medical profession were debarred from having an effective voice in the health services had always been a serious matter. Unless some steps were taken to bring the mass of the profession and those who knew about these things into responsible contact with those who, for the first time, were to take such a large part in administering the bill, the bill was little likely to have the good effects that were hoped for it. He recognized, however, that this clause gave the right of consultation, and he hoped that out of this poor beginning larger things would grow as the years went by.

The House agreed to Lord Onslow's amendment.

Drafting amendments were made in Clause 62 regarding the provision of hospital accommodation for infectious disease.

Other drafting amendments having been made, the Bill passed the House of Lords, and was returned to the House of Commons.

The Lords' Amendments considered by the Commons.

On March 22nd the House of Commons considered the Lords' amendments.

Mr. CHAMBERLAIN moved that the House should agree with the clause providing for consultation with representatives of the governing bodies and staffs of voluntary hospitals in its form as amended on the third reading in the House of Lords. He said that this was a matter of some importance, and had been considerably discussed in the House of Lords. The purpose of the discussion was to try to ensure that there should be full and ample opportunities for the representatives of voluntary hospitals in any area, including not merely the lay members but the medical and surgical staffs, to offer their experience and to put forward their views before the local authority set to work to revise its hospital accommodation. The Government did not desire to put into the bill more than was necessary, but it became clear in the House of Lords that people of very considerable weight and standing in the voluntary hospitals world were not satisfied that, without some statutory provision, there would be that measure of consultation with the representatives of the voluntary hospitals, which they felt to be not merely desirable, but vital for the proper development of the hospital services of the country in the future. With the object of the clause he had been always fully in sympathy. He had a very strong view that the assistance of the voluntary hospitals would be absolutely essential if the municipal hospitals, which would be reorganized and conducted by local authorities in future, were to be placed on a proper footing. They stood on a very different level from the voluntary hospitals, and it would be a work of time, care, and tact to bring them up, generally speaking, to the same level as that attained by the voluntary hospitals. That could only be done by the exercise of co-operation and good will on both sides. He believed that the provision made in the clause, under which there was the duty laid on the local authorities to consult with bodies representative of the voluntary hospitals, would bring about that co-operation and good will. It would be seen that the body which was to be consulted was such committee or other body as the local authority considered to be representative both of the governing bodies and the medical and surgical staffs of the voluntary hospitals. It would be said, perhaps, that in one area or another there would be no such body. It was quite possible that there was no such body in some areas now, but it was most desirable that there should be such a body, because the voluntary hospitals would never be able to exercise to the full the influence which they should on the health of the district unless there was co-ordination among themselves, and unless there was some body which would represent the various voluntary hospitals concerned, and which could speak for the whole of them when dealing with the local authority. Without such a body there would not be the full measure of consultation which was desirable. He regarded the clause, therefore, as likely to have the effect of stimulating the formation of such representative bodies, and from that point of view to be a valuable addition to the bill.

Mr. GREENWOOD said that to make the best use of the available hospital accommodation there must be consultation between the local authorities and the various voluntary hospitals, but he looked on the new clause with a little suspicion. The Minister of Health seemed to have in hand the organization of the new voluntary hospitals in the future with a view to preventing the development of the public hospitals. He saw no reason why the consultation proposed should not have been confined to the governing committees of the hospitals. Why should the local authorities have to consult the employees of the voluntary hospitals? The words of the new clause had been put in by the most powerful trade union in the country. They were initiated and supported by very influential members of the medical trade union.

Dr. FREMANTLE: What does the hon. gentleman mean by that? Does he mean the British Medical Association?

Mr. GREENWOOD: I mean the organized medical profession of this country.

Dr. FREMANTLE: Which organization does he mean?

Mr. GREENWOOD: There are more than one, I understand. I see no reason why the hon. gentleman should be ashamed of his trade union.

Dr. FREMANTLE: I am not ashamed of it, but I want the hon. gentleman to be precise in what he says.

Mr. GREENWOOD: To please the hon. gentleman I will say at once the British Medical Association.

Dr. FREMANTLE: May I ask if Lord Dawson has anything to do with the British Medical Association?

Mr. GREENWOOD: I should think it very unlikely; but no doubt he is a loyal paying member of his trade union, and is in a position to present its case in the House of Lords. Continuing, Mr. Greenwood asked why it should be made compulsory on the local authorities to consult with the servants of the voluntary hospitals. He was sorry that the Minister had lent himself to this new development of socialism in a very conservative profession. It looked as if there might be behind this proposal the opposition to any development which did not harmonize with their own particular interests.

Sir R. LUCE said that he welcomed the new clause, because some sort of co-ordination was essential in future between the voluntary system and the development of local authorities' hospitals if a great deal of overlapping was to be prevented. A vast amount of experience had been gained by the voluntary hospitals, not only in matters of administration, but in matters of co-ordination. There was need of the separation of different kinds of treatment, and a vast amount of work was necessary in reorganizing and co-ordinating to see that the right kind of work was done in the different hospitals throughout the country. That was a matter on which medical advice was necessary. Therefore it was a little unfair to say that the medical profession should not be consulted in this matter. He welcomed the clause very heartily on behalf of those interested in the development of the hospital system, and in the ensurement that, in any future extension of it, the wonderful old system of voluntary hospitals should not be elbowed out by processes of nature, but should remain the centre round which the new development of hospitals should proceed. They owed to Lord Dawson, who so eloquently and persistently urged the adoption of a clause of this kind, another debt of gratitude in addition to that which the nation owed to him to-day, and would never be able to repay him. (Cheers.)

Mr. PETHICK-LAWRENCE said that the Minister had given no indication of what the local authority would do in cases where no such committee as was contemplated by the clause existed. There was no obligation on the part of the voluntary hospitals to form such a committee.

Sir A. HOPKINSON said that he had had to deal with just such questions as were raised by the clause, which was an admirable one, and co-ordination was absolutely vital in hospital work and development. It was necessary that the medical staff should be consulted, for they were the people who really knew the points in question. In the co-ordination of hospital work in Manchester, of the governing body of which he was a member, the loyal co-operation of the medical men who had given their lives to this work had been of the utmost value. How could they possibly know what steps ought to be taken, not only in the matter of healing, but of research, unless they consulted the people who had been at work for years in connexion with the various hospitals? There was also the question of the training of medical men and nurses. On that point, after many years' experience, he had come to the conclusion that the co-operation of the laymen on the governing bodies, of the local authority, and of the trained medical men was vitally essential.

Sir H. NIELD said that, as one who had been interested in voluntary hospitals for many years, he thought that the attitude of the Opposition, who pretended to be the friends of the poor, was a very ungenerous one. He hoped that they would not hear any more of the ungenerous attacks on the medical profession, who had devoted their lives to the welfare of the public.

Sir H. SLESSER denied that anyone on the Opposition side had attacked the doctors. They all agreed in paying to the doctors the greatest possible tribute, and the question of their merits or demerits was nothing to do with the matter under discussion. The direction in the clause that the local authorities should consult with certain bodies was only a pious aspiration, for even if these bodies existed and consultations took place, nothing was provided as to the consultations being acted upon. The clause could not be interpreted in a court of law, and was meaningless.

Sir KINGSLEY WOOD said that in the House of Lords many most distinguished lawyers and judges who sat on the highest tribunal in the land had devoted considerable time to the discussion and framing of the clause, and he accepted their view that the clause was likely to have a real and practical effect. Its object was to avoid overlapping in the provision of hospital treatment, and he was certain that when the local authorities entered into consultation with the representatives of the voluntary hospitals those consultations would be of the friendliest nature. They would not be empty consultations, but really in the best interests of the poor and the sick of the country. A very large number of associations representative of the voluntary hospitals already existed, and where no such associations or committees existed at present the Minister of Health was assured that the voluntary hospitals would see that they were formed. It was obviously to their interests to do that. The local authorities and the bodies representing the voluntary hospitals could be trusted generally to consult in this matter in a friendly way, and to come to a conclusion which would be to the best interests of all concerned.

The new clause was agreed to.

A further amendment by the Lords, legalizing the practice of associations of wage earners and persons in receipt of small incomes to contribute weekly sums to the support of Poor Law hospitals as well as voluntary hospitals was agreed to. Mr. CHAMBERLAIN, in moving that the amendment should be accepted, said that in one case last year nearly £10,000 was paid to the guardians for services rendered by a Poor Law hospital.

Further amendments of a drafting character were made, and the bill was returned to the House of Lords.

London Lock Hospital.

Mr. CHAMBERLAIN gave a statement to Mr. Pethick-Lawrence and Mr. Arthur Greenwood regarding the London Lock Hospital. He said he had brought to the notice of the board of the hospital the recommendations of the committee appointed to inquire into the hospital. He had received an assurance, which he accepted, that the board had already applied itself to carrying the greater part of the recommendations into practical effect. This task must involve a comprehensive review of the constitution and management of the hospital and considerable time would be required to complete it. Mr. Chamberlain did not think it in the public interest to publish details of arrangements at the hospital which were already under revision by the governing body, if and so long as he remained satisfied at the extent of the changes made and the rate of progress in making them.

Mr. PETHICK-LAWRENCE asked Mr. Chamberlain to take into account that the inquiry was undertaken owing to serious allegations made against the board. He argued that the subscribing public was entitled to know whether the board was exonerated by the report, and, if not, whether the charges made were being met by the proposed alterations.

Mr. CHAMBERLAIN replied that the report of the committee showed that considerable changes in the management of the hospital were desirable. He had an assurance from the chairman of the board that it was addressing itself to making the necessary alterations.

Mr. PETHICK-LAWRENCE further asked whether, as the matter had been going on for some nine years, the subscribing public could not be expected to have any further confidence in the management unless there was real evidence of drastic changes.

Mr. CHAMBERLAIN agreed that the subscribing public would want to be assured that there were to be drastic changes. He had an assurance such changes were being made.

In reply to Mr. Pethick-Lawrence, on March 21st, Mr. CHAMBERLAIN said that he had no evidence of dissatisfaction with the reply which he had given some days previously about the report of the committee which inquired into the London Lock Hospital. He made himself responsible for ensuring that changes at the hospital were carried out with sufficient speed; but it was not practicable to impose a time limit. He could not undertake to publish the correspondence between himself and the board of the hospital.

The Puerperal Fever Death Rate.—In the House of Commons, on March 20th, during a debate on the motion for the second reading of the Consolidated Fund (No. 2) Bill, Mr. J. STEWART said that puerperal fever was still taking as large a toll of life as it did forty years ago. Apparently science, which had reduced the death rate in other directions, had failed in regard to this disease. He would like to know what action the Government was taking in the matter. It might be necessary for the central authority which was finding the money to use some sort of forceful persuasion on the local authorities to induce them to develop their maternity hospital accommodation. It should be possible for every woman at the time of childbirth to have the chance of the best accommodation and treatment. Sir JOHN GILMOUR regretted that greater progress had not been made in dealing with the very serious problem of puerperal fever, but they had taken steps to ensure that in future on every death certificate these facts should be notified, and that in itself would be an advance in giving them information, which could be tabulated. He would also draw attention to a report by Dr. Kinloch, the new head of the Health Department in Scotland, who spoke with peculiar knowledge on this subject. They desired to draw the attention of the whole medical fraternity to his report, which would be made available. He hoped by the steps taken recently in the Scottish Local Government Bill that they would make further progress in regard to the increase of hospital accommodation.

National Insurance: Osteopathic Treatment as an Additional Benefit.—Mr. HANNON asked the Minister of Health, on March 14th, whether his attention had been called to a resolution adopted, at its recent annual general meeting, by the National Federation of Employees Approved Societies, which emphasized the benefit to be derived from osteopathic treatment, and recommended such treatment as an additional benefit; and if he was prepared to consider favourably this suggestion provided treatment was given by competent qualified practitioners. Mr. CHAMBERLAIN replied that his attention had not previously been drawn to this resolution. A registered medical practitioner was not debarred from giving osteopathic treatment, if he thought fit, either under a special scheme approved by the Minister for the purpose of additional benefit or otherwise. If, however, Mr. Hannon suggested legislation to encourage the provision of such treatment by unregistered persons, Mr. Chamberlain could not undertake to regard the suggestion with favour.

Small-pox.—In a reply to Mr. Groves, on March 14th, Mr. CHAMBERLAIN said no experiments had been made at the Government lymph establishment with neuro-vaccine, which Mr. Groves described as recently brought into use on the Continent to replace the lymph of Jenner. No use had been made of this new vaccine for public vaccination purposes in England. Mr. CHAMBERLAIN stated, on March 21st, that the small-pox cases notified in London in the past three weeks were: Bethnal Green 2, Finsbury 4, Holborn 1, Islington 1, Lambeth 4, Poplar 9, St. Pancras 2, Southwark 3, and Stepney 13. He understood that 15 of those notifications were in respect of persons of 21 years or over.

Chlorodyne as a Drug of Addiction.—Lady ASTOR asked the Home Secretary, on March 13th, whether he was aware that fresh evidence of the use of chlorodyne as a drug of addiction had come to light since the Departmental Committee on Morphine and Heroin reported in 1926. Sir W. JOYNSON-HICKS replied that the evidence before the Home Office did not show that the abuse of chlorodyne had been increasing since the Rolleston Committee reported. Lady ASTOR asked whether the Home Secretary proposed at an early date to carry out Recommendation 103 (2) of this committee, which would secure that no preparation could be sold under the name of chlorodyne which contained more than 0.1 per cent. of morphine. Sir W. JOYNSON-HICKS said the recommendation of the Rolleston Committee had been under consideration, but legislation would be required to give effect to it. No opportunity for this had occurred, but the matter had not been lost sight of and was noted for consideration in connexion with the general question of the revision of the Pharmacy Act, which had been under investigation by a departmental committee.

Anthrax.—On March 14th Sir W. JOYNSON-HICKS said a warning of the dangers of anthrax, and the need for immediate recourse to medical examination, was required to be posted up by Home Office regulation in every tannery. Supplies of serum were available in every centre where the industries subject to this risk were carried on. The warning notice to which he referred enumerated the places where the serum could be obtained. Even in isolated factories a supply could always be available in a few hours. Any worker in the industry who was suffering from a boil or pimple or anything which might possibly be anthrax should obtain medical advice and treatment at once. In the case of a Liverpool tannery labourer, on whom an inquest was held on March 6th, neither the man himself, nor the welfare worker, nor the doctor suspected anthrax. He was not aware of an opinion among leather workers that cases of anthrax were due to inadequate inspection of raw hides. If he was given any information showing that serum was not available day and night he would have inquiry made.

Administration of Dangerous Drugs by Hospital Probationers.—On March 20th Sir R. THOMAS asked whether hospital probationers were entitled to administer powerful drugs, such as digitaline and morphine, in the absence of a qualified medical practitioner. Mr. CHAMBERLAIN replied that the administration of drugs within the scope of the Dangerous Drugs Act was subject to special restrictions, but the responsibility for administration rested with the medical practitioner in charge of the case. He could not undertake to decide in general terms who was to be held responsible in the event of the death of a patient as a result of a mistake on the part of a probationer. That must turn on the view taken of particular facts.

Certification of Insane Persons.—On March 13th Dr. VERNON DAVIES asked the Minister of Health if his attention had been drawn to the fact that, owing to a recent High Court case, medical men would not run the risk of certifying insane people. Dr. Davies asked, further, whether Mr. Chamberlain proposed to introduce legislation to deal with the situation, which was inimicable to the best interests of the afflicted persons and the public. Sir KINGSLEY WOOD said Mr. Chamberlain's attention had been drawn to this case. He hoped that any legislation which might be introduced to amend the lunacy laws would include a provision giving effect to the recommendation on this point of the Royal Commission on Lunacy and Mental Disorder.

Phthisis Attributable to Service in the Navy.—Introducing the Navy Estimates on March 14th, Mr. BRIDGEMAN said he had been concerned with the question of pulmonary tuberculosis in the navy and the awards of pensions to those suffering from it. After careful investigations, and with the sanction of the Treasury, the Board of Admiralty had adopted methods which made it easier for men to claim pensions for disease attributable to service. There were still, and would always be, cases on the borderline, but by the method adopted the number of cases recorded as attributable to service would increase.

Lead Paint Regulations.—On March 21st Sir W. JOYNSON-HICKS told Mr. Viant that, as a result of co-operation between the inspectors of his department and the Home Office, substantial progress had been made in compliance with the Lead Paint Act, 1926, and the regulations. As the regulations had been in force for less than eighteen months, it was not possible to form any reliable estimate of their efficiency. The Act was passed on the understanding that before prohibition was resorted to the effect of regulations should be tried, and he was not prepared to reopen this question at present.

Segregation of Mental Defectives.—On March 21st Mr. CHAMBERLAIN, answering Sir R. Thomas, said that the Mental Deficiency Acts of 1913 and 1927 already provided means by which mental defectives, including moral defectives within the meaning of the Acts, could be segregated or placed under guardianship or supervision. He saw no necessity for the appointment of a committee to advise on such segregation.

Notes in Brief.

The Minister of Health is considering the situation by the decision of Mr. Justice McCardie in Brown *v.* Dagenham Urban District Council, which allowed the dismissal of public officials at any time at the pleasure of the body employing them, irrespective of any contract about notice of termination of employment.

The amount of capital expenditure by local authorities on slum clearance schemes in the last five years is estimated roughly at £5,250,000.

Mr. Chamberlain estimates that in England and Wales during 1927 sickness benefit was paid under the National Health Insurance Acts for roughly 30,500,000 weeks, as against 28,250,000 in 1926, and 25,000,000 in 1925. Exact particulars are not available.

Mr. Chamberlain is inquiring into an allegation that a woman patient of Newark, Notts, was certified on account of delirium and sent to Radcliffe Asylum, where she was diagnosed as suffering from scarlet fever.

Universities and Colleges.

UNIVERSITY OF OXFORD.

DR. ORMOND ALEC BEADLE has been elected to a Dr. John Radcliffe Fellowship.

The Radcliffe Prize for the furtherance of medical science in the University has been awarded to Dr. Sidney Campbell Dyde.

UNIVERSITY OF LONDON.

THE degree of D.Sc. in Anatomy has been conferred upon Mr. W. B. Crow, of East London College, for a thesis entitled "Contributions to the principles of morphology."

An academic Diploma in Public Health is to be instituted.

Dr. M. E. Delafield has been appointed the representative of the University at the fourth Imperial Social Hygiene Congress, to be held in London in July.

Sir John Rose Bradford, C.B., has been re-elected vice-chairman of the University College Committee for 1929-30.

Dr. Harold Raistrick has been appointed, as from August 1st, to the University Chair of Biochemistry at the London School of Hygiene and Tropical Medicine, where he will also hold the position of Director of the Division of Biochemistry and Chemistry, as applied to hygiene.

UNIVERSITY OF LEEDS.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—*Part I*: Bessie Brown, W. H. Craven, H. Denton, C. H. Foster, J. F. Galpine, W. L. Hardman, J. N. Hill, G. M. Holliday, L. Hoyle, Eugenie C. Illingworth, I. J. Keidan, R. G. S. Meadley, C. Poniedel, L. J. Richmond, S. Rosenberg, S. Silman, L. Silverman, W. E. Smart, E. J. Wayne, J. W. Whitworth. *Part II*: J. Kak, J. Loofe, G. J. Marks. *Part III*: L. B. Flather, Esther M. Killick (with distinction in medicine), A. C. Shuttleworth, Ivy R. Watson.

M.SC. IN PHYSIOLOGY.—R. E. Tunbridge.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—*Part I*: V. T. Parkinson. *Part II*: Teresa Lightbound, V. T. Parkinson.

D.P.H.—*Part I*: A. B. Anderson, J. L. Clegg, Kathleen Edgecombe, R. R. Evans, Bridget M. O. Gordon, B. S. Jarvis, I. S. Jones, J. S. Logan, J. Macdonald, J. C. McFarland, R. L. McMorris, E. Miles, R. J. Ormsby, D. E. P. Pritchard, F. L. Smith, F. C. Speechly.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*Parts I and II*: W. H. Milligan, J. E. C. Walker, P. H. Whitaker, J. Wilson.

DIPLOMA IN TROPICAL MEDICINE.—K. B. Chakravarti, J. Crawford, W. C. Dale, J. R. Dogra, G. D. Drury, T. S. Gill, Margaret A. L. Herbertson, J. A. L. Innes, J. A. McGregor, W. B. McQueen, B. K. Majumdar, I. C. Middleton, J. T. F. Pearse, C. Ramdcholl, Elizabeth J. Robinson, P. B. Robinson, A. Shafi, T. Verghese, S. P. Wilson.

DIPLOMA IN TROPICAL HYGIENE.—S. W. H. Askari, A. Halawani, I. S. Hilmy, H. S. Lawrence, H. M. Setna.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., PART I.—*Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology, and Bacteriology.*—*S. H. Moore, *S. Levy, W. Caldwell, F. M. Lyons. (*In completion*): C. H. Hutchinson, A. A. Lisney.

PART II.—*Medicine*: A. F. Kennedy, L. B. Harris, F. R. Falkiner, T. B. McMahon, J. Beggs, P. A. Thornton, E. C. Hicks, N. Shapira, E. B. A. Solomons, G. B. Thrift, R. M. Wilson, M. E. Kirwan, N. S. Klass, M. H. Fridjhon, J. A. Dowds, C. King, N. H. Lindsay. *Surgery*: J. E. C. Cherry, N. Burstein, P. A. Thornton, Anna M. E. McCabe, H. Dundon, W. B. Hamilton, W. A. Y. Knight, Josephine M. Enright. *Midwifery*: *J. N. U. Russell, *E. F. St.J. Lyburn, *H. T. Fleming, P. O'Shea, R. E. Hemphill, Lilla M. Spiller, E. F. S. Morrison, G. R. Boare A. Rouse, Kathleen A. Wilson, S. Beggs, Dora G. Bradley, R. T. O'Shea, R. P. McGarrigle, Frances E. Wilson, N. Shapira, J. Willoughby, E. J. M. Bam.

DIPLOMA IN GYNAECOLOGY AND OBSTETRICS.—I. S. Marwah.

* Passed on high marks.

The Services.

NAVAL MEDICAL COMPASSIONATE FUND.

A MEETING of the subscribers of this fund will be held at the Medical Department of the Navy, Queen Anne's Chambers, Tothill Street, Westminster, S.W.1, on April 25th, at 11.30 a.m., to elect six directors of the fund.

INDIAN MEDICAL SERVICE.

THE following have been appointed to permanent commissions in the Indian Medical Service: K. F. Alford, H. J. Curran, A. M. Fraser, B. J. Griffiths, W. P. Lappin, E. A. Y. Mackeown, H. T. McWilliams, G. Milne, G. J. O'Connor, P. Sliannon, D. L. Trant, H. S. Waters, E. P. Walsh, W. J. Walsh. Further appointments are about to be made, and young medical men contemplating a medical career in India are referred to the announcement made in our advertisement columns.

DEATHS IN THE SERVICES.

Surgeon Captain Edward Leicester Atkinson, D.S.O., R.N., died suddenly at sea on February 20th, aged 46. He was born on November 23rd, 1882, the son of Edward Atkinson, Esq., was educated at the Forest School and at St. Thomas's, and took the M.R.C.S. and L.R.C.P.Lond. in 1906. In 1905 he won the light-weight boxing championship of the United Hospitals. Entering the navy soon after qualifying, in 1908-9, he served as vaccinator at the Royal Naval Hospital at Haslar, and in 1910 was appointed pathologist and bacteriologist to Captain Scott's expedition to the antarctic regions. When Scott set off for the South Pole he was left in charge of the ship, and commanded the main party at Cape Evans, and the party which went in search of the missing explorers, and found their bodies, buried them, and erected a great cairn over their remains. To the official account of the expedition, drawn up by Dr. Leonard Huxley, and published in 1913, he contributed a chapter entitled "The last year at Cape Evans," which concludes with the story of the finding of Scott's tents and the bodies of Scott and his companions, all except Captain Oates, whose remains were never found. In the great war Surgeon Captain Atkinson served successively with the Grand Fleet, with the Royal Naval Division in Gallipoli, and with a howitzer brigade in France, when he was thrice mentioned in dispatches, and received the D.S.O., and in North Russia in 1919. He was awarded the Albert Medal for rescue work in the explosion on H.M.S. *Glatton* in 1918, when he himself lost one of his eyes; and in 1920 he gained the Chadwick gold medal and prize, an award made every five years to the medical officer who has done the best special work for the health of the army and navy. So recently as last November he married Miss Mary Flint Hunter, daughter of John Hunter, Esq., of Glasgow.

Medical News.

AT a joint meeting of the Section of Psychiatry of the Royal Society of Medicine with the Medical Section of the British Psychological Society, to be held at 1, Wimpole Street, W.1, on Tuesday, April 9th, at 8 p.m., there will be a discussion on the role of anxiety in the psychoses and psychoneuroses. The speakers include Dr. Ernest Jones, Dr. H. Yellowlees, and Dr. R. D. Gillespie.

A SERIES of dances is being arranged by different London hospitals in turn in aid of the Royal Medical Benevolent Fund Guild, in the hall of the British Medical Association House, Tavistock Square, W.C.1. The first of these will be organized by Guy's Hospital, and will be held on Thursday, May 16th, from 8.30 p.m. to 12.30 a.m. Tickets, 6s. each, or 11s. for two, which include light refreshments, may be obtained from Mrs. Hale-White, 1, Portland Mansions, W.1; Miss V. S. Fripp, 19, Portland Place, W.1; or Mr. Winston, Medical School Office, Guy's Hospital, S.E.

A PUBLIC meeting to discuss developments of British chemical manufacturers will be held in the Mansion House, London, on Wednesday, April 24th, at 4.30 p.m., when Lord Melchett (president of the British Science Guild) will take the chair. The programme will include the following addresses: fertilizers from the air, by Sir Frederick Keeble; rayon (artificial silk), by Mr. A. B. Shearer; and synthetic drugs, by Mr. Francis H. Carr. Tickets for the meeting may be obtained on application to the British Science Guild, 6, John Street, Adelphi, W.C.2.

THE Library of the British Medical Association will be closed from the evening of Thursday, March 28th, until the morning of Tuesday, April 2nd.

ON March 25th the Westminster Bank transferred its Russell Square branch, at which the Association keeps its various accounts, to the North Wing of the Extension of the British Medical Association House in Tavistock Square.

A COURSE of post-graduate lectures will be delivered at the Royal Dental Hospital of London School of Dental Surgery, Leicester Square, W.C., commencing on Wednesday, April 10th, when Mr. Bowdler Henry will give a lecture-demonstration on the use and limitations of diathermy in dental surgery. On April 24th Professor J. C. Drummond will speak on certain biochemical aspects of saliva; on May 1st Dr. E. W. Fish will deal with the reaction of the pulp and dentine to caries; on May 8th Mr. J. G. Turner, F.R.C.S., will lecture on pain. The last lecture of the series will be given by Mr. F. St. J. Steadman, who will discuss fractures with special reference to treatment. The lectures, which begin at 6 p.m., are free to practitioners, advanced students, and others interested in the subjects.

THE Fellowship of Medicine announces that a two weeks' practitioners' course will begin on April 8th at the London Temperance Hospital in medicine, surgery, and the specialties from 4 to 5.30 p.m. daily. A series of eight lecture-demonstrations will be given at the London School of Tropical Medicine on Tuesdays and Fridays from April 9th, and a course of four lecture-demonstrations on light and heat therapy on Wednesdays at the Royal Free Hospital from April 10th. A three weeks' course in medicine, surgery, and gynaecology at the Royal Waterloo Hospital commences on April 15th. A course in neurology at the West End Hospital for Nervous Diseases will continue from April 15th to May 11th at 5 p.m.; it consists of lecture-demonstrations, illustrated by cases, and the minimum entry is 10. The Fellowship proposes to start a course for the July M.R.C.P. examination. Lectures will be given on diseases of the brain, nervous system, lungs, heart, blood, kidneys, alimentary system, and spleen, as well as on modern biochemical methods. Detailed syllabuses of these courses, information on post-graduate work in London at the general and special hospitals affiliated to the Fellowship, and copies of the *Post-Graduate Medical Journal* can be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Derby Medical Society has arranged a course of post-graduate lectures to be given by Dr. H. C. Cameron at the Derbyshire Royal Infirmary on Tuesday evenings at 8 p.m. The first lecture, on April 9th, will deal with the newly born, the second, on April 16th, with the infant and its diet, the third, on April 23rd, with acidosis, the fourth, on April 30th, with some surgical operations in childhood, and the fifth, on May 7th, with functional nervous disturbances. The fee for the course is £1 10s. Full particulars may be had from Dr. G. E. Kidman, 134, Osmaston Road, Derby.

As will be seen from our advertisement pages the next election to the Grocers Company scholarships for encouraging original research in sanitary science will take place in May next; they are of the value of £300, tenable for one year, but renewable. Forms of application can be obtained from the clerk of the Grocers Company, Grocers' Hall, E.C.2, to whom they must be returned before the end of April.

QUEEN CHARLOTTE'S Maternity Hospital has now decided to purchase a site of five acres on the Goldhawk Road, near Ravenscourt Park Station, in the borough of Hammersmith. Building operations will commence at an early date on the first section—a separate isolation block (with research facilities) for patients suffering from puerperal fever. This will be the first instance in this country where reception will be provided on a large scale for cases of puerperal infection, and where laboratory research and the training of post-graduate students and midwives can be based upon the study of such cases.

LISTS of medical practitioners serving as members of local authorities or their subsidiary public bodies in Great Britain were published in our issues of December 8th (p. 1057) and December 29th, 1928 (p. 1190), and February 16th, 1929 (p. 314). We have since received intimation that Dr. S. Edwards Jones (Wrexham) is chairman of the Public Health and Small-pox Hospital Committees, a member of the Maternity and Child Welfare Committee and of the Mental Deficiency Committee, and a representative of the Voluntary Hospitals Committee of the Denbighshire County Council. In the Borough of Wrexham Council he is deputy mayor and alderman, and chairman of the Health and Child Welfare Committee, and was mayor in 1910-11. He is a member of the Wrexham Rural District Council and chairman of the Joint Fever Hospital Committee; also a member of the Wrexham Board of Guardians, of which he was for seven years chairman. We have also been informed that Dr. Alex. A. Carruthers is a member of the Parish Council of Shilton, Warwickshire.

THE late Sir Hector Clare Cameron of Glasgow left personal estate of the value of £34,723. He bequeathed the portrait of himself by George Henry, R.A., to the Royal Faculty of Physicians and Surgeons of Glasgow, and £100 to the Western Infirmary, Glasgow.

SIR ROBERT ARMSTRONG-JONES of Plas Dinas has been elected sheriff for Carnarvonshire for 1929.

THE following appointments have recently been made in foreign faculties of medicine: Professor Dubois, dean of the faculty of medicine, and Dr. Ingelrans, professor of therapeutics, at Lille; Dr. A. Barraud, professor of the oto-rhino-laryngological clinic at Lausanne; Dr. Wilhelm Brock, professor of oto-rhino-laryngology, and Dr. Otto Goetz of Frankfort, professor of surgery, at Erlangen; Professor von Eicken, director of the oto-rhino-laryngological clinic, dean of the medical faculty, and Dr. Rõszle of Basle, professor of general pathology and pathological anatomy, at Berlin; Dr. Karl Reuter, professor of medical jurisprudence at Breslau; Dr. Terracol, professor of oto-rhino-laryngology, and Dr. Riche, professor of gynaecology, at Montpellier; Professor A. Fornesco, director of the obstetrical and gynaecological clinic at Cagliari; Dr. Otto Steurer of Tübingen, professor of oto-rhino-laryngology at Rostock; Dr. Eugen Ludwig, professor of anatomy at Basle; Dr. Grasbey, pro-
[illegible] ne; Dr. Holfelder, professor
[illegible] Dr. I. Nasso of Perugia,
[illegible] at Messina, in succession to Professor Cannata, who has been transferred to Palermo; Dr. I. Simon of Pavia, professor of pharmacology and toxicology at Padua; Dr. Salva, professor of clinical ophthalmology, and Dr. Sigaud, professor of anatomy at Grenoble; Dr. de Leobardy, professor of medical pathology and experimental medicine at Limoges; Dr. Quinquaud, professor of physiology at Rheims; Professor Dr. von Haberer, rector of the medical academy at Düsseldorf; Dr. Joseph Schuller of Cologne, professor of pharmacology at Göttingen; and Dr. Guido Fanconi, professor of children's diseases at Zürich.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963,* and *9964* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

PIGMENTATION OF THE FACE.

"HOPEFUL" asks for advice in the treatment of a female patient, aged 38, who for many years has been distressed by a dark brown staining of the skin below the eyes.

ANOREXIA NERVOSA.

"LOWLANDER" would like suggestions for the treatment of a woman, aged 21, suffering from anorexia nervosa of one year's standing. The patient weighs only 5 st., has no appetite, and is constipated. Drugs have no effect on her condition, though ultra-violet rays have brightened her mentally. She has been twice in hospital.

EMISSION WITHOUT ORGASM.

"PRAC." writes in answer to "M.B., B.S." (March 2nd, p. 429): I do not know of such a case as this in normal people, but have known of involuntary emission without orgasm in a case of adolescent dementia.

THE TRIANGULAR BANDAGE.

DR. N. CORBET FLETCHER (London, N.W.) writes: In reply to the query of "Inquirer" (New Zealand) (March 23rd, p. 585), the triangular bandage was invented about 1850 by Dr. Mayer of

Lausanne (Switzerland). It was popularized by Dr. Esmarch of Kiel, who introduced its use to the German army about 1875, and it was brought in 1877 from Germany to England by the St. John Ambulance Association. Dr. Mayor published in 1831 a book called *Fragments of Popular Surgery*, in which he praised the utility of handkerchiefs which, as he said, "can be cut diagonally into triangular bandages," or, as he called them elsewhere, "three-cornered bandages." In an appendix he described various ways in which the triangular bandage may be (and still is) used. The book was translated from the French by Dr. Thomas Cutler, and published in this country in 1836.

ENURESIS.

DR. T. W. HILL (London, N.W.) writes: In reply to "K.'s" query (March 9th, p. 485), and the replies it has evoked, allow me to give my large experience of similar cases at the Willesden clinic. In the great majority of cases each of the usual practices for the relief of this distressing complaint proves futile, whether it be circumcision, removal of adenoids, sleeping on hard boards, belladonna, etc. The only sure method i[illegible] on the part of the mother, reinforced by [illegible] child. It is my custom when any case [illegible] inquire into the mother's efforts to stop the habit. If there has been punishment or disapproval of any kind, this is promptly stopped. There must be absolute co-operation between parent and child, otherwise success is impossible. How can anyone speak of a sense of shame concerning an action which occurs in sleep, and which is similar to sleepwalking and sleep-talking? A complete psychological investigation is necessary into any source of worry or anxiety (frequently scholastic), and a regime of hope and encouragement introduced. It has been my practice to give the child a chart marked with the days of the week, which should be hung above his (her) bed. For each dry night a star is placed in the corresponding space. This scheme is derived from the American psychologists and proves extremely successful in practice. In about 90 per cent. of cases bedwetting ceases within two months, the time varying according to the duration and severity of the habit.

ILLNESS FOLLOWING A SHAMPOO.

DR. W. U. D. LONGFORD (Holywood, co. Down) writes: On March 4th a patient of mine went to a hairdresser's for a dry shampoo. She was warned by the attendant to hold a towel over her nose "as some people faint." Almost immediately the shampoo was applied the patient collapsed, and, I believe, the attendant was also partially overcome. My patient was carried out of the small compartment to another room with an open window, where the staff tried to revive her. After an hour's massage she had not recovered, so they sent for her mother, who took her home in a taxicab. The patient told me that she never lost consciousness completely, but that she was unable to move a limb or speak. When I saw her she appeared dazed, as if recovering from an anaesthetic, and there was a strong smell of the chemical which had been used as a shampoo. Three days later she was still weak and unable to stand; she complained of severe headache, and her systolic blood pressure was only 95. Not until March 9th was she able to leave her bed, and even now she has not completely recovered, though her blood pressure is 120. I have been unable to discover the nature of the chemical used in the shampoo or any reference to similar cases in available medical literature, but I have a vague recollection of reading of a fatal case of the same kind some years ago.

*** It is possible that the chemical used in the shampoo which caused such serious effects on our correspondent's patient was carbon tetrachloride, which was formerly employed with some freedom in shampoos and brought about the fatal case of which our correspondent has a faint recollection. It is possible that the hairdressing fraternity has also nearly forgotten this case, and has consequently revived the use of this very poisonous compound, which is closely allied to chloroform, but more toxic.

INCOME TAX.

Replacement of Car.

"N. S. P." bought a 12-h.p. car six years ago for £600 and has now sold it for £45, and bought another car at a price of £316. What should he claim?

*** The amount of the actual out-of-pocket cost—that is, £316 – £45 = £271.

"J. D. McC." has claimed obsolescence in respect of a 12-h.p. A car bought in 1924 and replaced by a car of similar make and power bought on January 1st, 1928. The inspector of taxes declines to give effect to an obsolescence allowance because the replacement of the old 12-h.p. A car by another 12-h.p. A car is not within the statutory rule.

*** We consider that the claim is well founded. Having regard to the purpose for which a car is required by a medical practitioner and the wear and tear it suffers, there is nothing abnormal in the contention that a car is "obsolete" for the use to which it is being put in three years. The inspector appears to be putting an interpretation on the word "obsolete" which it is not intended to bear. The judge's dicta in the case of South Metropolitan Gas Company *v.* Dadd support our view, though his decision—on the special facts of that case—was in favour of the Revenue.

LETTERS, NOTES, ETC.

TREATMENT OF INFLUENZA.

DR. TRESSIE PIRES (Burnham-on-Sea) writes: I was much interested by Dr. W. Bastian's account on March 9th (p. 455) of the aspirin, phenacetin, and ipecac. treatment of influenza. After reading Dr. Garry Simpson's note on March 2nd (p. 439) with regard to this powder, I tried the same on a patient, who described its effect as very beneficial after the sweating; the headache and pains in limbs disappeared, and a second dose gave complete relief. Surely, at least, the excess of toxins causing the acute symptoms is here eliminated by the skin—shown by the fall in temperature and the feeling of well-being that the patient experiences—in spite of the fact that the bronchial and nasal secretion, even of a muco-purulent nature, which may continue, gets rid of the rest of the toxic process and debris of cells. I should like to know what dose is effectual in children.

SUDDEN DEATH FROM PNEUMONIA WITHOUT APPARENT SYMPTOMS.

DR. G. DUDLEY (Stourbridge) records another fatal case of symptomless pneumonia in an infant, following that reported by Drs. J. A. Stephen and E. R. C. Walker on January 26th (p. 152). He writes: A male infant, weighing 4 lb., was born two months prematurely on May 29th, 1928; with careful feeding on breast milk and good general nursing the child gradually gained weight and thrived. At the age of 6 months the weight was about 8 lb. and the child appeared to be doing well. About this time the mother had to go into hospital for an operation, and the child was looked after by an aunt. On December 5th, 1928, the infant was seen by a health visitor, who expressed herself as satisfied with his progress. The next day the father went to work at 7 a.m. and left the child asleep and apparently well, but two hours later I was called to the house and found the child dead. There was no evidence from external examination as to the cause of death and there was no history of any recent illness. There was a slight petechial rash round the buttocks which was said to have been of recent origin. At the necropsy the right lung was found to contain large patches of broncho-pneumonia, and there were a few recent pleural adhesions; the spleen was enlarged and the pulp was soft. The other organs appeared healthy. Death appears to have been due to extreme toxaemia, but the interest lies in the suddenness of the event.

PHYSIO-THERAPY IN CHRONIC RHEUMATISM.

DR. J. CAMERON (Beverley) writes: Dr. Frank D. Howitt, in his informative paper on physio-therapy in the treatment of chronic rheumatism (February 23rd, p. 338), refers to Dr. Percy Wilde's book on the pyretic treatment of rheumatism in connexion with the elimination of lactic acid. Dr. Howitt says a condition of hyperthermia quickly follows the immersion of the body in a hot bath, etc., and, further, that "vapour baths" give the best results in rheumatic cases. I have carefully read Dr. Wilde's work, and the essence of his thesis seems to be that in his particular vapour bath the air is simply "saturated" at the temperature concerned; that there is no free "condensed" vapour in the atmosphere of his bath; and that therein lies its efficiency, contrasted with the ordinary vapour bath, the atmosphere of which, while "saturated" for the temperature concerned, is also clouded with "condensed" vapour—in fact, one would say the condition alleged in the Wilde bath is that of the atmosphere in the Red Sea when the temperature is well above 90° F. and the air, of course, "saturated." I wonder if Dr. Howitt has made any comparison of the two conditions—that is, if there *is* a difference—and if he is able to say if there is any real difference in clinical results. If not, then a simple "cure" would be the Red Sea voyage, which I have done several times, or a run to Basra up the Persian Gulf, or anywhere to a hot "saturated" climate.

A CENTIPEDE IN THE NOSE.

MR. A. P. BERTWISTLE (London, W.) writes: There are some points in which I beg to disagree with Dr. Gordon Wilson in his article in the *British Medical Journal* of March 9th (p. 446). The common centipede (*lithobius*) is a much stouter, keratinous insect, possessing sixteen pairs of legs, whilst the millipede, which this closely resembles, has many more legs. I admit, however, that there is a centipede found in the South of England not unlike the one illustrated (*geophilus*). The life-history of both insects is about a year; I do not see how it could have hatched in the nose. Furthermore, these insects do not leave the soil to visit flowers. I suggest the patient got the adult creature into his nose, a favourite habitat, while breaking stones. Dr. Wilson mentions some interesting features of blow-fly infections. I have heard, and seen, one case which suggests that if, before the advent of suppuration, the wound is so infected, it will not become septic. If this is so, would it not be possible to prepare the ideal antiseptic from the maggot? It is quite feasible that maggots take precautions that their food supply shall be preserved against putrefaction.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, and 48 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 76.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

310. Nervous Complications of Whooping-cough.

M. GIUFFRE (*Arch. de Méd. des Enf.*, February, 1929, p. 82), who records an illustrative case seen in the children's hospital at Palermo, states that a much larger number of cases of whooping-cough with nervous complications have been described in northern than in southern countries. Nervous symptoms usually appear in the paroxysmal stage. In addition to convulsions and spasm of the glottis, which some writers regard as symptoms of latent tetany, forms of cerebral paralysis have frequently been described, accompanied or not by bulbar symptoms and involvement of the special senses. It is rarer to meet with clinical meningitis, disseminated sclerosis, Friedreich's ataxia, Landry's ascending paralysis, and pseudo-tabes, while sensory changes have only been found in association with other symptoms. A few instances have been recorded indicating a spinal lesion giving rise to flaccid paralysis with involvement of the sphincters and sensory changes, or polyneuritis. The psychical changes include dementia, idiocy, and night terrors. As regards the pathogenesis, little importance can be attached to the mechanical factor (increase of intravenous pressure during the attack of coughing) in comparison with the action of the toxins of the Bordet-Gengou bacillus. Some writers maintain that the nervous complications of whooping-cough only occur in children who are subjects of spasmophilia. Pathological investigations have shown that haemorrhages in the central nervous system are much rarer than was supposed. Sometimes no naked-eye lesion has been found, but merely degenerative changes in the nerve cells. Neurath found considerable meningeal infiltration with mononuclear leucocytes accompanied by hyperaemia and very small haemorrhages. Giuffre's patient was a female infant, aged 15 months, who developed left spastic hemiplegia preceded by convulsions limited to the left side of the body during the paroxysmal stage. Complete recovery followed at the end of two months after treatment by lumbar puncture, protein injections, and magnesium sulphate, and bromide preparations internally.

311. Etiological Factors in Leprosy.

G. W. ST. C. RAMSAY (*Trans. Roy. Soc. Trop. Med. and Hyg.*, November, 1928, p. 249) reports that leprosy is very prevalent in Southern Nigeria, the incidence in certain densely populated districts being above 3 per cent. He has collected a series of 616 patients, of whom 68.34 per cent. were males; their ages ranged from 8 to 60, and the average duration of the disease was 6.1 years. The maculo-anaesthetic variety of leprosy accounted for 80.5 per cent. of all cases in this series. Scabies was found in 32 per cent. of patients, mostly children, and Ramsay suggests that this condition may provide foci through which leprosy bacilli gain entrance to the body, and should be considered an important factor in the etiology of leprosy. Blood films revealed the presence of *Microfilaria perstans*, *M. loa*, and *M. bancrofti* in approximately one-sixth of all the cases. Examination of faeces showed a high percentage of hookworms, ascarides, and whip-worms. Entozoa are so prevalent in West Africa that the natives appear to possess a relative acquired immunity to the effects of these parasites. Nasal smears were taken in all cases. The nodular and mixed types of leprosy had a very high infectivity rate; but less than 10 per cent. of the maculo-anaesthetic cases were actively infectious. A positive Sachs-Georgi reaction was found in 42.7 per cent. of the cases. This represents the combined syphilis and yaws percentages, but confirms the general medical opinion that syphilis is extremely prevalent among Southern Nigerian natives. Ramsay agrees with authorities in India that arsenobenzol treatment should be given to every leper who has a positive Sachs-Georgi reaction. He advocates the establishment of voluntary leper colonies by medical missions aided by Government grants.

312. Pathogenesis of Pernicious Anaemia.

J. MEINERTZ (*Deut. med. Woch.*, February 8th, 1929, p. 218), after discussing the symptoms of pernicious anaemia, concludes that, if the raised haemolysis is primary and the disturbance of the marrow activity is secondary, extirpation of the spleen is suggested, since this organ is the haemolyser of used-up and injured red cells. The results of splenectomy are: (1) raising of the haemoglobin and red cell count, so that the colour index approaches normal; (2) enormous influx of normoblasts immediately after the intervention; (3) the appearance of Howell-Jolly bodies; (4) immediate increase in the number of leucocytes, especially lymphocytes; and (5) marked eosinophilia. The course of the disease is altered so that the characteristic crises and remissions are no longer differentiated; those therapeutic measures which failed to act before the splenectomy are now beneficial, and the megalocytes, which were more readily affected by the haemolytic action of the spleen, have now an extended life. The removal of the spleen has also a direct and lasting stimulus on the bone marrow, as illustrated by the increased number of leucocytes. The effect of liver treatment is a complete restoration to health, which, however, is not permanent, the symptoms returning sooner or later if the administration is stopped. The author considers that the disease interferes with the function of the liver in dealing with the toxic waste products of amino-acid oxidation. He concludes that the nature of the disease is a qualitative irregularity of the bone marrow activity, by which more readily haemolysed red cells are produced. By liver treatment the blood picture more nearly returns to normal than by treatment with arsenic, blood transfusion, or by splenectomy, in which the characteristic megalocytosis remains.

313. Idiopathic Pleural Effusions.

M. HÄUTEMANN (*Zeit. f. Tuberkulose*, January, 1929, p. 483) reviews the literature and records his observations on 250 cases of pleurisy admitted to the Neukölln Hospital from 1920 to 1927; 80 of these cases were regarded as of tuberculous origin. After careful examination only 45 of the patients could be found with no obvious signs of tuberculosis to be detected by clinical or radiological methods. An inquiry was made into the subsequent history of the patients; 15 could not be traced, 10 had developed rapidly progressive pulmonary tuberculosis from which 3 had died, while the remaining 20 were in excellent health and showed only the residues of a past attack of pleurisy on physical and x-ray examination. Häutemann comes to the conclusion that in two-thirds of all cases of the so-called idiopathic pleurisy this symptom is the only manifestation of an otherwise latent tuberculous infection, and that the favourable prognosis of the condition is due to the immunizing and bactericidal properties of the pleural effusion. In the great majority of cases of this type of pleurisy there is pulmonary infiltration.

Surgery.

314. Surgical Treatment of Angina Pectoris.

IT has now been fully established that painful stimuli arising in or near the heart may be modified by closing the pathways along which they travel to the central nervous system, and E. P. RICHARDSON and P. D. WHITE (*Amer. Journ. Med. Sci.*, February, 1929, p. 161) compare the results following sympathectomy and paravertebral alcohol injection in angina pectoris. Sympathectomy was first performed by Jonnesco, who advocated the bilateral removal of the whole cervical sympathetic chain, including the first thoracic ganglia. Later, Coffey and Brown reported successful results following removal of the superior cervical ganglion only. For the purpose of comparison the present authors treated four cases by each method, all the eight cases being comparable as regards the seriousness of the anginal condition. In the one series the operations, limited to the left side, were removal of the superior cervical ganglion, of the superior ganglion and sympathetic chain down to the first thoracic ganglion, and of the inferior cervical and first thoracic ganglia, which form the stellate ganglion. The other series, treated by the method of Swetlow, included two cases of coronary thrombosis, which would not have been suitable operative risks. The authors conclude that the results obtained from sympathectomy are not encouraging, and that the relief occasionally obtained involved too great a risk to the patient. Symptomatic relief was more constantly secured by paravertebral injections; the tendency to recurrence after this method is offset by the possibility of repeating the treatment. This procedure is safer than sympathectomy, and is considered to be the first method of choice for angina pectoris when other measures have failed. Injection, generally of the left upper five thoracic nerve roots, is recommended in obstinate cases, and there seem to be no contraindications.

315. Tannic Acid Treatment of Burns.

A. H. MONTGOMERY (*Surg., Gynecol. and Obstet.*, February, 1929, p. 277), from an experience of 24 cases of burns in children, advocates treatment with tannic acid, regarding it as a real advance upon any other method in respect of the reduction of mortality. After a dose of morphine sufficient to control pain the surrounding skin is cleansed with benzene or ether, gross particles of dirt being removed with sterile instruments. A freshly prepared 5 per cent. solution of tannic acid in water is then sprayed over the wound and the child is placed in bed on a sterile sheet without clothes or dressings of any kind, a tent being made with blankets with one or two electric lights suspended from the roof for warmth and drying. The spraying of the wound is repeated every half-hour, and in from fifteen to twenty-four hours a dry brown crust has formed, completely sealing it. After the first half-hour the wound becomes and remains painless. Fluids are given by mouth, hypodermoclysis, or proctoclysis, with, in severe cases, glucose or blood transfusion intravenously, and the child is kept under the tent without any further local applications. At the end of three or four days all evidence of toxaemia has usually disappeared. In superficial burns the crust begins to loosen at the edge as epithelization proceeds, and the loosened portion can be cut away with scissors. In deeper burns the crust usually loosens in from two to three weeks, leaving a granulating surface which can be prepared for grafting by wet saline or Dakin's solution dressings. Advantages claimed are the reduction of scar formation to a minimum, absence of pain, freedom from dressings, the obviation of large weeping wounds, and lessening of toxaemia.

316. Cholecystitis with Haematemesis.

P. MOULONGUET (*Bull. et. Mém. Soc. Nat. de Chir.*, January, 1929, p. 15) remarks that, although gastric haemorrhage occurs frequently in cases of gall-stones accompanied by jaundice, yet a severe haematemesis without jaundice but associated with cholecystitis is not so common and sometimes obscures the diagnosis. These haemorrhages, although occasionally of little significance, may produce a grave condition, due either to their profusion or to their association with acute infective phenomena round the biliary tract. In many cases the occurrence of a gastric haemorrhage suggests the presence of a lesion of the digestive tract, but if, during operation, no abnormality of the stomach or duodenum is found, the biliary tract must be examined. In grave gastric haemorrhage with acute cholecystitis surgical intervention is an urgent necessity. The symptoms may be very diverse in these cases; there may be a profuse haematemesis or only a continuous oozing of blood and an occult melaena. Sometimes there are severe and frequent haemorrhages with considerable haematemesis and melaena. Frequently these severe attacks of bleeding, when allied to the acute infection of cholecystitis, render the prognosis very grave, through anaemia and the results of the infection causing toxic absorption. The pathology of these haemorrhages is interesting since it is so varied. There are said to be four causes: alteration in the constitution of the blood; duodenal erosions and inflammation of the duodenum; thrombosis and aneurysm of the hepatic artery; and haemorrhage into the gall-bladder or bile ducts.

317. Cervical Ribs.

A. RECCIUS (*Zentralbl. f. Chir.*, January 26th, 1929, p. 211), who records an illustrative case in a woman aged 27, states that cervical ribs are most often found in the female sex. The condition is often accompanied by other malformations, such as scoliosis, torticollis, rachischisis, club-foot, or retained testes. Of these, scoliosis, which Streissler found in 16 per cent. of his cases, is the commonest malformation, and involves the lowest cervical and upper dorsal vertebrae. Other concomitant congenital abnormalities that have recently been recorded are horseshoe kidney, absence of sacrum, presence of lumbar ribs, and pseudarthroses of the clavicle. Cervical ribs are also frequently associated with nervous diseases, especially exophthalmic goitre, syringomyelia, and tachycardia. Although the symptoms may naturally appear at any age, their onset is commonest between 20 and 30, owing to the ossification of ribs at this time. In many cases, however, other causes have been responsible, such as trauma or diseases of the ribs themselves. Nervous symptoms, in the form of paraesthesia and pain, first attract attention, and are aggravated by pressure on the cervical plexus or sudden turning of the head. Paralyses as a rule are uncommon; irritation of the sympathetic is manifested by mydriasis, widening of the palpebral fissure, and exophthalmos. Circulatory disturbances of all degrees, ranging from a feeling of chilliness and cyanosis to gangrene of the fingers, may occur. The difficulty of diagnosis is shown by the fact that of Trostler's 63 cases only 17 were correctly diagnosed. In 28 cases the first diagnosis was neuritis, and in 9 progressive muscular atrophy; in another 9 instances the cervical ribs were discovered by accident. When the diagnosis is doubtful an *x*-ray examination is decisive. In most cases associated with symptoms operation is indicated.

318. Poliomyelitis following Tonsillectomy.

W. L. AYCOCK and E. H. LUTHER (*New England Journ. of Med.*, January 24th, 1929, p. 164) record sixteen cases of poliomyelitis, in patients aged from 3 to 25 years, in which the paralysis occurred from seven to eighteen days after tonsillectomy, so as to suggest a causal relationship between the operation and the subsequent paralysis. In answer to the suggestion that the medical practitioner who removed the tonsils was a carrier, and infected the patient at the time of the operation, the authors point out that, with one exception, no two cases in their series were operated on by the same man. In one city where four cases occurred three were operated on by the same practitioner, but at different times. Since poliomyelitis was prevalent at the time, and the physician had performed more than 200 tonsillectomies during the period, the authors are not inclined to associate the cases with the operator, but suggest that the disease may follow the operation, because this procedure opens up the pathway for the virus which may already be present in these individuals.

Therapeutics.

319. Indications for the Administration of Calcium.

H. O. COLOMB (*Med. Journ. and Record*, February 6th, 1929, p. 121), discussing calcium metabolism from the therapeutical standpoint, states that the mere ingestion of calcium salts is insufficient to overcome their lack in the body since the metabolism of this metal has been found to be influenced by phosphates, vitamins A and D, and the internal secretions of the parathyroid and thyroid glands and the anterior pituitary lobe. Calcium is present in all tissues of the body as a necessary physiological salt in some form, either in an organic or in an inorganic combination. Its therapeutical indications are classified as: (1) conditions resulting in jaundice and its concomitants, toxaemia, haemorrhage, and pruritus; (2) those accompanied by intestinal toxaemia; (3) those associated with gastro-intestinal ulceration and a tendency to haemorrhage; (4) those resulting from the introduction of exogenous toxic agents with reduction of the available blood calcium—for example, oxalate and mercury poisoning, the results of intravenous injection of citrates and tartrates and iodide coryza; (5) rickets, hypoparathyroidia, and infantile tetany, in which calcium is indicated as an adjuvant to other therapy, and the essential etiological factor of which is a deficiency in vitamin D accompanied by a lowering of the blood phosphorus and calcium; and (6) those conditions of sympathetic or parasympathetic inequilibration and closely associated with anaphylactic phenomena, including hay fever, asthma, urticaria, serum rashes, frost-bite, angioneurotic oedema, and hyperaesthetic rhinitis. The metabolism of calcium is intimately associated with that of phosphates, and is regulated to some extent by the vitamin D and the parathyroid internal secretion. The metal has a marked affinity for nitrogen and nitrogenous products, and physiologically it is essential to the permeability of the plasma membrane, to the coagulation of the blood, to the rigidity and repair of the bony structures, and to the stability of nervous tissue, due to its fixation of phosphates.

320. Intracardiac Blood Transfusion.

BESIDES the introduction of drugs into the heart, C. ACHARD, A. COURNAND, and Mlle PICHOT (*Bull. de l'Acad. de Méd.*, January 29th, 1929, p. 129) state that it is possible to inject sufficiently large amounts of liquids, such as artificial serum or incoagulable blood, into that organ, and thus to perform an intracardiac transfusion. They believe that this exceptional method of urgency will be found expedient in such cases as those of profuse haemorrhage with a danger of imminent death when intravenous injection is impossible owing to collapse of the veins. The authors report a case in which this method met with brilliant results. A woman suffering from typhoid fever seemed to be at the point of death following one small and two profuse intestinal haemorrhages. Since the veins were collapsed an intracardiac injection of 2 mg. of adrenaline and 400 c.cm. of citrated blood was made at the sternal border of the left third intercostal space. Improvement ensued almost immediately, and after further treatment by subcutaneous injections of camphorated oil, caffeine, sparteine, and artificial serum the patient made an uninterrupted recovery. Another point of interest in this case was a delayed agglutination reaction, this becoming positive only on the fifty-second day of the disease.

321. **Combined Iodine and Sulphur.**

ARMINGEAT (*Rev. de Méd.*, 1928, No. 7, p. 967) claims that the association of iodine and sulphur gives much better therapeutic results, especially in sclerotic conditions, than are obtained when either is administered separately. He points out that many disadvantages attend the use of iodine and iodized preparations, and that there is very little definitely known regarding the action of sulphur. In order to act efficiently, sulphur must be combined and not in the oxidized form. The iodine and sulphur should be combined in a single organic chemical compound, which permits of a maximum simplicity of usage with minimum chances of oxidation. Substances of this nature are thiosinamine, which owes its antisclerous property to the sulphur combined in its molecule, and the old "oil of Haarlem," which is really a synthetic sulphuretted oil. For this form of treatment Armingeat suggests the name "thiodotherapy," and states that remarkable results have followed its use in such diseases as tabes, medullary scleroses, chronic rheumatism, angina pectoris, and emphysematous conditions; it is said to be valuable also in ophthalmology, oto-rhino-laryngology, and urology.

Radiology.

322. **X-Ray Diagnosis of Primary Pulmonary Neoplasms.**

B. P. STIVELMAN (*Journ. Amer. Med. Assoc.*, December 1st, 1928, p. 1690) thinks that the frequency of primary pulmonary malignant conditions has markedly increased during the past twenty-five years, authentic data revealing an incidence as high as 9.4 and 15.5 per cent. of all primary malignant growths. This increase has been ascribed to various causes; the inhalation of tar particles and gasoline fumes, and the influenza pandemic, have been suggested as possible etiological factors. Stivelman mentions a few cardinal symptoms which, while not pathognomonic, are of diagnostic value; these are blood-spitting, dyspnoea, severe and prolonged pain in the chest, and afternoon elevation of temperature. There is no general agreement as to the histogenesis of malignant lung tumours, but it is recognized that pulmonary carcinoma is synonymous with bronchial carcinoma, early pulmonary malignant growths being endobronchial in at least 85 per cent. of the cases. From the radiological viewpoint Stivelman divides primary pulmonary neoplasms into the pulmonary and the pleural; the former are further classified as endobronchial, hilar, lobar, and excavating; and the latter according as an effusion is present or absent. The radiology of these various types is discussed, and the author insists that in early cases tumours near the hilum and those which spread along the bronchial tree cannot be diagnosed without an *x*-ray examination. Early bronchogenic tumours which have not grown large enough to obstruct the bronchus and flat pleural tumours may, however, be missed in such an examination, though physical observations may point to their existence. Central tumours, regardless of their point of origin, are visible radiologically long before other methods of examination will suggest their presence. If large effusions are present tumours cannot be diagnosed by *x* rays unless the fluid is aspirated and a pneumothorax induced, when the radiograph will indicate the contrast between the growth and the surrounding tissue. Spontaneous free or interlobar empyemas and pulmonary abscesses not of metapneumonic origin, when they occur in persons past middle life, are in themselves suggestive of a possible malignant condition. In difficult cases for a correct diagnosis *x*-ray films must be taken in oblique positions; bronchography with iodized oil is helpful, and, particularly, early bronchoscopy must be employed.

323. **Radiological Diagnosis of Cardiac Diseases.**

L. G. RIGLER (*Minnesota Med.*, January, 1929, p. 25) states that organic heart disease usually produces enlargement of one or all the chambers of the heart, and a change in size and shape results. Recognition of enlargement is often the deciding factor in making a positive diagnosis of heart disease, and the determination of shape may aid greatly in diagnosing the type of pathology present. Radiology is the most accurate means of defining the exact size and shape of the heart. Visualization of the oesophagus may assist in the diagnosis, as it may be compressed and displaced by enlargement of the left auricle. Disease of the mitral valves produces essentially three *x*-ray findings: a distinct increase in the transverse diameter of the heart, a marked convexity of the left border due to the conus pulmonalis, and a posterior displacement and compression of the oesophagus in that portion which is in contact with the left auricle. Disease of the aortic valves and hypertension produce practically the same radiological findings. Essentially these are: a marked concavity of the left border of the heart, increase in the transverse diameter, prominence of the left ventricle, and a general enlargement (late) of the whole heart with the left ventricle predominating. Thyroid insufficiency may give rise to a flask-shaped heart, which rapidly decreases in size during thyroid medication. Toxic conditions of the myocardium produce the same kind of heart. Chronic lung conditions may result in a cardiac enlargement the shape of which is similar to that of the mitral heart, but oesophageal displacement is absent.

324. **Radiation Treatment of Hyperthyroidism.**

B. L. W. CLARKE (*Med. Journ. of Australia*, December, 1928, p. 670) describes the results he has obtained by deep *x*-ray therapy in a series of 44 cases of hyperthyroidism, 37 of the patients being women and 7 men. He advocates preliminary rest in bed for about a fortnight, during which he administers Lugol's solution for about ten days. He usually gives a total exposure of four to five hours, in various stages over a period of two to four weeks. He has given an hour's exposure each time, but occasionally even half an hour proved to be excessive. The rays were generated at 200 kilovolt peak, with 4 to 5 milliamperes of current, filtered through copper and aluminium. Clarke finds that *x*-ray sickness can be controlled by rest in bed, the administration of alkali and soda-water, and the local application of ice packs. The treatment of the neck with lead lotion after each irradiation is recommended. The author stresses the importance of prolonged rest in bed after the course is completed, to allow damaged heart muscle to recover. He records 18 cases as being apparent cures of from two to five years' duration, and 13 cases of definite improvement, though the heart was not quite normal. The treatment was of no value in 7 cases; 5 patients were lost sight of, and one girl, aged 17, died of cardiac failure following intense *x*-ray sickness after the second dose.

Obstetrics and Gynaecology.

325. **Puerperal Scarlet Fever.**

V. DE LAVERGNE and A. FRUHINSHOLZ (*Gynécol. et Obstét.*, December, 1928, p. 450) discuss the problem of scarlatiniform eruptions occurring during the puerperium. From a consideration of the literature on the subject and their own observations of such cases they conclude that there may exist a specific puerperal scarlatina, different from true scarlet fever which may also occasionally complicate the puerperium. Certain cases of puerperal scarlatina appear to have their path of infection by way of the genital tract. These cases are notable for the absence of the typical buccopharyngeal picture of a true scarlet fever, in which it is admitted that the principal mode of infection is by droplets. During labour and the puerperium the genital mucosa is particularly exposed, and if any attendant should be a carrier of virulent droplets the way is prepared for a puerperal scarlatina. These observations appear to bear out the hypothesis known as the "phenomenon of Cantacuzène," which suggests that scarlet fever is due to the combined action of an ultra-virus and a streptococcus. Streptococci are frequently found in the cervix, and if an attendant supplies the ultra-virus the result will be a puerperal scarlatina. Further evidence is adduced from considerations of epidemiology. The peculiar characteristic of puerperal scarlatina is that several patients are infected at the same time. Recently at the Nancy Maternity Hospital two women presented signs of scarlet fever on the same day; there had been no case in the hospital for several months. The patients did not occupy adjacent beds, nor did they know each other. The simultaneous eruption could only be explained by supposing that one of the hospital staff was a carrier of the virus. It has also been noticed that the puerperal scarlatina does not spread like an epidemic in a school or military establishment, the cases being generally concentrated within twenty to thirty days. The impression given is that it does not pass so much from one patient to another as by means of some carrier. True scarlet fever, on the other hand, spreads in a centrifugal manner; there is a record of a professor, a house-physician, students, and pupil midwives having been infected from one original patient.

326. **Arthropathies of the Menopause.**

H. J. LAUBER (*Zeit. f. Chir.*, February, 1929, p. 335) refers to the recent literature describing cases of arthropathy, especially of the knee- and finger-joints, occurring among women at the menopause, and asserts that the majority of these joint changes are of purely endocrine origin. Some German writers have described cases of exophthalmic goitre, accompanied by severe arthritic lesions, which were cured

or greatly improved after irradiation or excision of the thyroid gland. Such cases are said to be rare, but arthropathies due to ovarian dysfunction are seen much more frequently. In a typical case, in addition to the usual hot flushes, headaches, and menstrual irregularity, the patient complains of severe articular pains, usually most marked in the fingers and knees. Indefinite tingling sensations and aching pains occur in the limbs, due to vasomotor spasm. Thermal factors, such as changes in the weather, and, in many cases, frequent immersion of the hands in cold water, aggravate the symptoms. The etiology of the arthropathy is indefinite. The improvement that follows, in many cases, the administration of ovarian preparations is held to confirm the theory of endocrine deficiency. The vasomotor spasm appears to initiate degeneration in the para-articular tissues. Lauber recommends the administration of ovarian preparations, potassium iodide, and alternating hot and cold baths. The secondary periarthritis may develop into a chronic destructive process, or, later, secondary arthritis deformans may occur.

327. Tuberculous Salpingitis simulating Ruptured Tubal Pregnancy.

K. A. MEYER and A. F. LASH (*Journ. Amer. Med. Assoc.*, February 2nd, 1929, p. 330) report a case in which necrosis caused by tuberculosis of the Fallopian tube gave rise to the clinical picture of a ruptured tubal pregnancy. A woman, aged 26, was admitted to hospital with severe abdominal pain, a blood-stained vaginal discharge, and amenorrhoea of one month's duration. Apart from two previous attacks of severe pain she had had no localizing symptoms, but for the previous ten years she had had pleuritic pain in the chest, accompanied by cough, slight fever, and nasopharyngitis. At the operation a considerable quantity of liquid blood, with clots, was removed from the pelvic cavity, and firm fibrous adhesions were found, the tubes being nodular and bound down. Bilateral salpingectomy was performed and convalescence was uneventful. The correct diagnosis was established by microscopical section of the Fallopian tube, no chorionic wandering cells or decidual reaction being present; pregnancy could thus be ruled out. A marked tuberculous infiltration of the endosalpinx was discovered; rupture had occurred in an area filled with tubercles. There were no changes in the breasts or uterus, and no corpus luteum of pregnancy. The tubal tuberculosis was secondary to peritoneal disease which had apparently healed. The haemorrhage was not only free in the peritoneal cavity, but had dissected the peritoneum over the bladder and the broad ligament, thus giving rise to the pain in the left lower portion of the abdomen and the tenderness over the bladder. The authors remark that, though the clinical picture of a ruptured Fallopian tube with intraperitoneal haemorrhage is usually due to tubal pregnancy, it should be remembered that inflammation, nutritional disturbance of the tube, and the dragging of adhesions on it may occasionally produce a local decrease in its resistance, with consequent rupture and haemorrhage.

Pathology.

328. B.C.G. and Immunization.

F. GERLACH and R. KRAUS (*Zeit. f. Immunitäts. u. exp. Therap.*, 1929, vol. 59, p. 305) have conducted a series of protective experiments on *Macacus rhesus* monkeys, using Calmette's B.C.G. The inoculation of this strain in a dose of 1/10 mg. intracutaneously into the eyebrow of two monkeys proved comparatively harmless; only a small inflammatory nodule developed, which showed no tendency to enlarge, and which underwent spontaneous retrogression. This is in marked contrast with the inoculation of the ordinary virulent mammalian strains, which give rise to tuberculous abscesses in the neighbourhood, enlargement of the cervical glands, and ultimately to generalized tuberculosis. It was also found that the subcutaneous inoculation of 50 mg. of the B.C.G. strain caused no progressive lesions. In the first protection experiment two monkeys were inoculated each with three doses of 10 mg. of B.C.G. subcutaneously, the three doses being given within a fortnight. Five weeks after the last dose 0.05 mg. of a virulent bovine strain was inoculated intracutaneously into the eyebrow of each of the monkeys. Two other monkeys, each of which had received a single dose of 50 mg. of B.C.G. subcutaneously forty-six days beforehand, were inoculated with the same dose of virulent bacilli. A similar injection was made into two unvaccinated control monkeys. The four vaccinated monkeys remained perfectly well, showing nothing but a small non-progressive, non-ulcerating local lesion; of the control monkeys one died three months later, and the other was killed about the same time; both of them showed generalized tuberculosis. In the second experiment three monkeys were protected with a single dose of 50 mg. of B.C.G., and three were used as controls. All were injected with 0.1 mg. of a virulent human strain. The vaccinated monkeys remained well; of the controls one died in a month, one in about three months, while the third was killed after three months; all of them showed generalized tuberculosis. In the third experiment three vaccinated and two control monkeys each received 1/100 or 1/20 mg. of virulent human bacilli. The vaccinated [illegible] the controls one died and the [illegible] months; both showed generalized tuberculosis. From these experiments the authors conclude that the B.C.G. strain can give rise to undoubted immunity to experimental tuberculosis.

329. Phagocytosis of Haemolytic Streptococci.

R. HARE (*Brit. Journ. Exper. Path.*, 1928, vol. ix, p. 337) describes a series of experiments on the phagocytosis of haemolytic streptococci of high and low virulence by the blood of patients infected with that organism. Todd has shown that haemolytic streptococci which are virulent for mice are able to multiply freely in normal human defibrinated blood, and that the converse of this is true. Consequently Hare defines the term "virulent" as the ability to survive and multiply in normal human defibrinated blood. In the experiments described it was found that the leucocytes in the defibrinated blood of patients infected with haemolytic streptococci ingest virulent strains of these organisms in greater numbers than do the leucocytes of normal persons, and that this phagocytosis is due to a high opsonic power in the serum. This opsonic power is heat-stable, resisting 55° C. for thirty minutes. Little attention has formerly been paid to these opsonins, owing, possibly, to the usual employment of avirulent strains, and it would seem advisable in future studies of immunity in streptococcal infections to employ virulent cultures. The addition of small quantities of serum containing heat-stable opsonins to normal defibrinated blood causes a materially reduced rate of growth of virulent haemolytic streptococci; this is due to increased phagocytosis of the microbes by the leucocytes. Hare discusses the possibility of utilizing this property for the treatment of established or imminent infections by the use of the serums of convalescents or immunized animals. But since ordinary antistreptococcal and antiscarlatinal serums apparently do not contain these heat-stable opsonins, it seems that some special conditions must be fulfilled for their production in animals.

330. The Relation of B. pseudotuberculosis rodentium to B. pestis.

S. I. ZLATOGOROFF and B. I. MOGHILEWSKAJA (*Ann. de l'Inst. Pasteur*, December, 1928, p. 1615) have endeavoured to find out what methods are most useful in distinguishing *B. pseudotuberculosis rodentium* from *B. pestis*. Working with two strains of the former organism, they found that the basal colony type was smooth, but that in old broth cultures rough colonies appeared having a dull wrinkled surface and a crenated or lobate edge. Morphologically the smooth colonies consisted of short bacilli, often displaying well-marked bipolar staining; the rough colonies consisted of larger, often longer, organisms not showing bipolar staining. Biochemically both types of variant fermented the same sugars, but if the results were recorded from twelve to thirty-six hours after inoculation of the media it was noticed that the smooth variants produced acid rather more slowly than the rough. Using Otten's test, it was found that if the organisms were grown in a medium containing 0.05 per cent. glucose the reaction in the cultures inoculated with the rough type first became definitely acid and then returned to neutral, or became slightly alkaline, after seven days; in cultures seeded with the smooth type the same initial acidity was observed, but the return to neutral occurred more slowly, so that after seven days the reaction was only just neutral or was slightly acid. Virulence experiments made on guinea-pigs led to the conclusion that the smooth type was more virulent than the rough; but this difference, though evident in one strain, was hardly observable at all in the other. Serological experiments, using the complement-fixation test, indicated that the smooth and the rough types were antigenically dissimilar. From their observations on the dissociation of *B. pseudotuberculosis rodentium* the authors conclude that most of the differential tests separating this organism from *B. pestis* have been worked out on rough types of *rodentium*. They point out that these tests do not serve to separate the smooth type of *rodentium* from *B. pestis*. The demonstration of the close relationship existing between these two organisms—a relationship that is even closer than has hitherto been suspected—opens up, the authors consider, a new range of epidemiological problems concerning the genesis of plague in rodents.

RHEUMATOID-ARTHRITIS
LUMBAGO SCIATICA
NEURITIS

ALL THESE CONDITIONS YIELD RAPIDLY TO A COURSE OF

ELIXIR FORMASAL CO. AND TAB. ARTHRITONE

The combined treatment is giving excellent results in cases of Rheumatoid Arthritis which have stubbornly resisted all other forms of medication.
The results that are being obtained by the profession are very striking, and no practitioner can afford to be without a supply.

Please note, our preparations are not advertised to the public.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

JB 94

Prescribed in numerous cases *of* ***nervous and heart disorders, also rheumatic conditions,*** *etc.*

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Bath Rusks

Unsolicited testimonials daily for Carr's famous Bath Rusks, which are ideal for babies and young children.
Scores of letters from grateful mothers

Made by

CARR'S of Carlisle

This preparation is now obtainable in 5-oz. bottles.

MIST. HEPATICA CONC. (Hewlett's).

Composition.—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does NOT come under the Dangerous Drugs Act.

THIS excellent compound has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease, and in pregnancy or in the constipation due to sedentary habits, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient, and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz.; 10-oz.; 22-oz.; 40-oz; and 90-oz. Bottles. Price in England, 12/6 per pound.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

PUBLIC NOTICE

re

"RYVITA CRISPBREAD"

and

"THE RYVITA CRISPBREAD HABIT"

We acknowledge with much pleasure and grateful thanks the volume of congratulations on our successful introduction of "Ryvita Crispbread" to the British Isles.

When we gave to the British public this new and invaluable food—creating throughout our country the *Ryvita Crispbread habit*—we started what has now become almost a revolution in the bread-eating habit of the nation.

"Ryvita Crispbread" is the successful outcome of generations of experience directed to making just this one thing *right*.

That it is, and does, all that we claim for it is proved by the welcome it has received from Doctors, Dentists, and food experts, who not only prescribe it but have it as the daily bread in their own homes.

Because of its success, not only with the professions and the experts, but with the ordinary folk of these islands, there have arisen a number of "imitation Crispbreads." Some of these are not bad—*as imitations*—some are bad, some quite bad.

We make "Ryvita Crispbread" in Sweden because this type of bread is essentially and characteristically Swedish. The special ovens which we use are a mere item compared with the skill and long experience needed to make Ryvita *right*. It has taken generations of experience devoted exclusively to making just this type of bread to win the present perfection of "Ryvita Crispbread."

Although we make "Ryvita Crispbread" in Sweden, we who own and control the Ryvita Company are British. We buy British when it is best. But, like most other British people, we *will* have the best.

When we smoke a cigar it must be—Havana made in Cuba. After dinner, when we offer our friends a glass of port—it must be port from Portugal. When we have a little party, our champagne must be genuine from France. The suggestion that you should buy imitation Crispbreads merely because they are "British made" is as ludicrous as it would be to claim pre-eminence for British Cigars—British Port—or British Champagne.

Whilst the Ryvita Company is proud of its achievement in popularising the healthful *Ryvita Crispbread habit* in this country, it entirely dissociates itself from these hastily prepared substitutes.

The genuine original "Ryvita Crispbread"—crisp, scrunchy, and delicious . . . . the bread of life and health—helps to make indigestion, constipation, malnutrition, and obesity unknown.

"Ryvita Crispbread" is sold by all good grocers and stores at 1/6 per 40–50 slice (1 lb.) carton; ½ lb. carton, 10d.

The Twenty h.p. Rolls-Royce

"The 20 h.p. Rolls-Royce is noteworthy because of its design, quality and performance. These are, literally, well nigh perfect and its behaviour is the proof. Acceleration and top-gear performance rob the driver of handling his gear lever out of necessity—gear changing, in fact, must be a pastime, not a duty, when it is undertaken. But even when such unnecessary operations are undertaken the driver's ear will be left unaware of his action. Acceleration is as smooth as velvet and as powerful as the iron hand under the proverbial glove. Steering is light and true, and the brakes as faultless in effect as any that designers of the future will ever invent.

Rolls-Royce makers breed their car for perfection—or rather, since they are the first people to say their cars are not perfect, "quality" is the keynote of their production. With perfection as their goal, this firm is in the forefront of the race."

Vapo-Cresolene
Est. 1879
Sold by Chemists
Write for descriptive Booklet No. 67A.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.
There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

NEURASTHENIA
BELVOIR NURSING HOME, ASTON-ON-TRENT, DERBY.

Private Nursing Home for Neurasthenia and allied Functional Nervous Disorders, for general Convalescent Cases, and those requiring Electrical Treatment.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, Ultra-violet Light, and Massage is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week. For further particulars apply to—
Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: *Shardlow* 16.
Dr. Douglas-Morris can be seen by appointment in London.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BEECHY ROGERS, Secretary.

Can anyone recommend a PRIVATE SCHOOL

for a well-mannered, intelligent, but backward boy of 13 years, from Petit Mal and Enuresis? He has had troubles and frequently retires to bed. He would require careful nursing. A house within easy reach of Norwich would be preferred.—Reply to Dr. I. D. DICKSON, 23, Unthank Road, Norwich.

Lowestoft and North Suffolk HOSPITAL, LOWESTOFT.

HOUSE SURGEON (male), preferably with knowledge of X-ray. Salary £120 per annum, board, residence, and laundry. Applications, with copies of three recent testimonials, to the Honorary Medical Superintendent, April 10th.

County Council of Durham.

DISTRICT TUBERCULOSIS MEDICAL OFFICER.

The County Health Committee invite applications for a District Tuberculosis Medical Officer, at a commencing salary of £600 per annum, rising by annual increments of £25 to £650 per annum. Travelling expenses will be paid by the County Council.

The appointment will be held subject to three months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered medical practitioner between the ages of 25 and 45 years, must devote the whole of his time to the duties of the office, and must not engage in private practice.
(2) He should have held a House appointment for at least six months in a General Hospital and have had practical experience in the treatment of tuberculosis in sanatoria and otherwise.
(3) He will be attached to the County Health Department, and will, subject to the directions of the County Medical Officer, be under the control of the Central Tuberculosis Medical Officer.
(4) He will be required to reside in his Dispensary area, or such other centre as required by the Council.
(5) He will be required to carry out the duties of a District Tuberculosis Medical Officer.
(6) He must be prepared, if called upon, to act as Locum Tenens to other members of the Medical Staff of the County Medical Officer.
(7) The holding of a Diploma in Public Health, and practical experience in bacteriological laboratory work, will be deemed additional qualifications for the post.

The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, endorsed "District Tuberculosis Medical Officer," with copies of not more than three recent testimonials, must be forwarded on or before April 5th next to the County Medical Officer, Shire Hall, Durham, from whom forms of application can be obtained.

Shire Hall, Durham. March 18th, 1929.
HAROLD JEVONS, Clerk of the County Council.

Administrative County of Southampton.

COUNTY MEDICAL OFFICER OF HEALTH.

The Hampshire County Council invite applications for appointment of County Medical Officer of Health from persons legally qualified for the practice of medicine, surgery, and midwifery, and registered in the *Medical Register* as holders of a Diploma in Sanitary Science, Public Health or State Medicine, under Section 22 of the Medical Act, 1886, and of an age not exceeding 45 years at the date of application. The post is established for purposes of superannuation.

The person appointed will be required to devote the whole of his time to the duties of his office and not to hold any other appointment or engage in private practice.

He will receive a salary of £1,250, payable monthly, and all sums by way of fees or otherwise received by him will be paid over to the County Fund.

He will be provided with the necessary offices and clerical staff.

Applications on a prescribed form (which with further particulars of duties and conditions of appointment may be obtained from me), addressed to me and endorsed "County Medical Officer," must be delivered at the Castle of Winchester on or before April 20th.

Canvassing, either directly or indirectly, is prohibited and will disqualify.

The Castle, Winchester. March, 1929.
F. V. BARBER, Clerk of the County Council.

City and County of Newcastle-upon-Tyne.

CITY HOSPITAL FOR INFECTIOUS DISEASES.

RESIDENT MEDICAL ASSISTANT (Male).

Wanted immediately, a Resident Medical Assistant (male) who holds a registrable qualification in Medicine and Surgery (and preferably also in Public Health), and possesses a practical knowledge of Bacteriology.

Salary £350 per annum, with board, lodging, &c.

Applications, stating age, qualifications, and previous experience, to be forwarded with copies of not more than three recent testimonials to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

March 19th, 1929.

Liverpool Port Sanitary Authority.

ASSISTANT PORT MEDICAL OFFICER.

The Corporation of the City of Liverpool, as Port Sanitary Authority, require the services of an Assistant to the Medical Officer of Health, whose duties will be in connection with the Tidal Inspection of Vessels, the Medical Inspection of Aliens, and such other duties as may from time to time be assigned to him.

The salary will commence at £700 per annum, increasing to £800 per annum by annual increments of £50.

Candidates must possess a registrable Medical and Surgical qualification, and should hold a *Diploma in Public Health*, and their age must not exceed 35 years.

The person appointed will require to devote whole-time service to the duties specified, and will be subject to the Superannuation provisions of the Liverpool Corporation Act, 1921.

Canvassing of members of the Council is strictly prohibited.

Applications, stating age, qualifications, and past experience, accompanied by copies of recent testimonials, should be addressed to the Chairman of the Port Sanitary and Hospitals Committee, under cover to the undersigned, and delivered not later than April 5th.

Envelopes to be endorsed "Assistant Port Medical Officer."

Municipal Buildings, Liverpool. *March 16th, 1929.*
WALTER MOON, Town Clerk.

Nottinghamshire County Council.

APPOINTMENT OF SCHOOL DENTIST.

Applications are invited for the appointment of a whole-time School Dentist at a salary of £500 per annum, rising after two years' satisfactory service by increments of £25 to a maximum of £550. Travelling expenses will be paid in addition according to the scale approved by the County Council.

Candidates must be fully qualified and registered Dentists, and the person appointed will be required to perform such duties as may be from time to time prescribed by the County Education Committee, and to devote his whole time to the duties of the office. He will be a member of the staff and act under the control and direction of the County Medical Officer of Health, and required to reside in a part of the County to be approved by the Education Committee.

The appointment will be terminable by three months' notice on either side.

Application, on the prescribed form (which may be obtained on application to me), accompanied by copies of not more than three recent testimonials, should be forwarded to The County Medical Officer, Shire Hall, Nottingham, not later than April 10th.

Shire Hall, Nottingham. March 23rd, 1929.
K. TWEEDALE MEABY, Clerk of the County Council.

Borough of Bexhill.

MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified gentlemen for the appointment of Medical Officer of Health of the Borough, subject to the provisions of the Public Health Officers Act, 1921, and the Sanitary Officers Order, 1925.

The gentleman appointed will be required to perform all the duties imposed on a Medical Officer of Health, to act as School Medical Officer, and to carry out all such duties as the Council, with the consent (if necessary) of the Minister of Health, may from time to time direct. He must reside in the Borough and devote all his time to the duties of the office, and must not engage in private practice.

The salary to cover all the duties specified above will be £800 per annum inclusive.

Applications, stating age, experience, etc., accompanied by copies of not more than three recent testimonials, should reach the undersigned not later than April 6th, endorsed "Medical Officer."

Town Clerk's Office, Bexhill. March 19th, 1929.
S. J. TAYLOR, Town Clerk.

The Miller General Hospital,

Greenwich Road, S.E.10.

CASUALTY OFFICER (male and unmarried) required. There are four other residents. Salary £150 per annum, with board, residence, and laundry. Duties to commence on or as soon after April 1st as possible.

Applications, stating age, nationality, qualifications, and experience, accompanied by copies of not more than three recent testimonials, to be sent to the Secretary as soon as possible.

March 25th, 1929.

County Borough of Bournemouth

ASSISTANT MEDICAL OFFICER (Woman).

Applications are invited for the above appointment at a salary of £600 per annum, subject to deductions under the Council's Superannuation Scheme.

Candidates must be registered medical practitioners and possess a Diploma of Public Health, and under the age of 40. The officer will be expected to:

(a) Conduct Child Welfare, Ante-Natal and Post-Natal Clinics;
(b) act as Inspector of Midwives;
(c) supervise Nursing Homes;
(d) inspect and treat children in Secondary and Elementary Schools (experience in Refraction will be considered an additional qualification);
(e) perform such other duties as may be directed by the Council.

The successful candidate will be required to act under the supervision and control of the Medical Officer of Health.

Applications (with photograph if desired), stating age, qualifications, and previous experience, accompanied by copies of three recent testimonials, should be sent to the undersigned not later than April 20th.

Application forms will not be provided, but further information as to the duties, if required, may be obtained from the Medical Officer of Health.

Town Hall, Bournemouth. *March 23rd, 1929.*
HERBERT ASHLING, Town Clerk.

Borough of Keighley.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The Keighley Borough Council require the services of an Assistant Medical Officer of Health and Assistant School Medical Officer at an inclusive salary of £600 per annum.

Candidates must be registered medical practitioners of at least three years' standing, and hold the D.P.H. or equivalent qualification, and also have practical experience in the duties of a School Medical Officer and Maternity and Child Welfare. Experience in Refraction, Ultra-violet Light, and Orthopædics will be considered an additional qualification.

The candidate appointed must devote his or her whole time to the duties of the office, and he or she will not be allowed to engage in private or consulting practice. The candidate will be required to reside in the Borough of Keighley.

Applications upon the prescribed form, which may be obtained from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), must be sent to me on or before April 9th, endorsed "Assistant Medical Officer."

The appointment will be determinable by three months' notice on either side.

Canvassing, either directly or indirectly, will disqualify.

Town Clerk's Office, Keighley. March 19th, 1929.
S. WALKER, Town Clerk.

West End Hospital for Nervous Diseases.

In-patient Department: Gloucester Gate, Regent's Park, N.W.
Out-patient Department and Secretary's Office: Welbeck Street, W.

The Committee of Management invites applications for the appointment of Two HON. ANÆSTHETISTS. Further particulars should be obtained from the undersigned, to whom it is requested that 12 copies of the application and testimonials may be sent not later than Monday, April 22nd.

J. P. WETENHALL, Secretary.

Royal Isle of Wight County Hospital, Ryde.

A vacancy having occurred in the office of HONORARY SURGEON to the Ear, Nose, and Throat Department, the Election Committee of the Governors will proceed to fill the appointment. Candidates must not be engaged in general practice. Further details may be obtained from the Secretary, to whom applications must be addressed, and should be received not later than Wednesday, April 10th. Canvassing members of the Election Committee will be a disqualification.

A. S. GORDON, Secretary.

Worcester General Infirmary.

JUNIOR RESIDENT MEDICAL OFFICER wanted. Applications from candidates are invited, stating age, qualifications, experience, and whether married or single, with copies of recent testimonials (not more than two), to reach later than April 5th. Salary £120 per annum, inclusive, with board, residence, and washing.

E. J. HOLLAND, Secretary.

Administrative County of East SUFFOLK.

APPOINTMENT OF WOMAN ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from registered woman medical practitioners for the above appointment.

The duties of the post include the Medical Inspection of School Children, Maternity and Child Welfare work, and Clinical and Tuberculosis work. Experience in Refraction is *essential* and the possession of the Diploma in Public Health will be a recommendation. The person appointed will be required to devote the whole of her time to the duties of the office.

The salary attaching to the post will be £600 per annum. A deduction of 5 per cent. for superannuation will be made, and motor car allowance will be paid on the Council's scale for use of the officer's car.

The person appointed will be required to pass a medical examination, and the appointment will be subject to three months' notice on either side.

Applications are to be made upon a form, which can be obtained from the County Medical Officer of Health, County Hall, Ipswich, to whom the completed forms should be returned not later than Monday, April 15th.

County Hall, Ipswich. CECIL OAKES, Clerk of the County Council.
March 25th, 1929.

East Riding County Council.

ASSISTANT TUBERCULOSIS OFFICER.

Applications are invited for the post of Assistant Tuberculosis Officer under the East Riding County Council.

The gentleman appointed will be required to live at the Raywell Sanatorium (64 beds), where he will be Medical Superintendent. He will also be expected to carry out the duties of Clinical Tuberculosis Officer within the County.

The salary is at the rate of £650 per annum, with emoluments valued for superannuation purposes at £100 per annum, subject to the statutory deductions under the Local Government and Other Officers Superannuation Act, 1922. The emoluments are a bungalow, rent, and rates free, also fuel, light, laundry, and garden produce.

Applications, accompanied by not more than three recent testimonials, must be made on prescribed forms, which can be obtained on application, and must reach the undersigned not later than Saturday, April 13th.

(Signed) J. R. PROCTER, Clerk of the Council.
County Hall, Beverley. March, 1929.

The King Edward VII Welsh NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered medical practitioners (male) for the post of AREA TUBERCULOSIS PHYSICIAN. Salary £500 per annum, rising by annual increments of £20 to £700 per annum (plus Civil Service bonus), with a guaranteed total minimum salary of £750 per annum, together with travelling and subsistence allowances when absent from base.

Applications, stating full qualifications and previous experience, together with copies of three recent testimonials, should reach the undersigned not later than Tuesday, April 2nd.

Memorial Offices, Westgate Street, Cardiff. D. A. POWELL, Principal Medical Officer.

Hampshire County Council.

ASSISTANT COUNTY MEDICAL OFFICER (TEMPORARY).

Applications are invited for the post of Assistant Medical Officer of Health (Temporary). The duties comprise general public health work, including medical inspection of school children in Secondary and Elementary Schools; and work under the Tuberculosis Scheme and the Maternity and Child Welfare Scheme, etc. Salary at the rate of 10 guineas per week, together with travelling and subsistence allowances.

Form of application may be obtained from the County Medical Officer, The Castle, Winchester.

Bootle Borough Hospital.

APPOINTMENT OF HON. DERMATOLOGIST.

Applications are invited for the above vacancy. Candidates are requested to send particulars of their qualifications and experiences, accompanied by testimonials, addressed to the Secretary-Superintendent, Bootle Borough Hospital, Derby Road, near Liverpool, not later than Friday, April 12th.

Tynemouth Union.

ASSISTANT MEDICAL OFFICER (Non-resident).

The Guardians of the Tynemouth Union invite applications for the appointment, for a period of six months, of an Assistant Medical Officer for their Poor Law Institution, Preston Road, North Shields, and for the Children's Homes of the Union.

Salary £300 per annum, inclusive of vaccination and all other fees. The officer appointed will be required to pay to the Common Fund of the Union all fees received by him for Inquests, certifying lunatics, etc., to devote the whole of his time to the duties of the office (which includes the training of Probationer Nurses), to reside in close proximity to the Institution, and to act under the direction of the Medical Officer.

Applicants must be duly registered under the Medical Acts, and be qualified by law to practise in Medicine and Surgery in England and Wales, and the candidate appointed will be required to produce his licences, diplomas, or certificates to the Guardians.

The appointment is subject to the provisions of the Poor Law Officers Superannuation Act, 1896.

Applications must be made on a printed form, which will be sent on receipt of a stamped addressed foolscap envelope, and must be returned to me, accompanied by copies of testimonials as to professional ability and personal character, by the first post on Saturday, the 7th proximo.

By Order,
Guardians' Hall, North Shields. TOM PERCIVAL, Clerk to the Guardians.
March 25th, 1929.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 / 1783}

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. DEATH VACANCY.—NORTHANTS.—Country district, near large town.—Mixed-class PRACTICE, producing about £1,200 p.a., including panel of 800. Fees 5/6 to 10/6, with medicine extra. Midwifery 2 to 5 guineas, about 20 cases yearly. Excellent well-built house, with 3 reception, 10 bedrooms, etc. Garden, garage. Price for freehold £2,500, £1,500 of which on mortgage. Hunting, shooting, fishing, etc. Schools within reach. Premium one year's purchase, or near offer.
2. KENT—COAST TOWN.—Small, but increasing middle and working-class PRACTICE, producing for last 12 months nearly £600. Panel of 560. Visits 3/6 upwards. Not much midwifery at from £3 3s. Double-fronted eight-roomed house, with three-quarters of an acre of garden. Price for freehold £1,400. Premium £900.
3. DEATH VACANCY.—WEST MIDLANDS, CATHEDRAL CITY.—Old-established good mixed Practice, producing for last 12 months about £900, including panel of over 1,000. Fees 5/6 to 10/6. Midwifery from 3 gns. Good house situated in best part of town, with 2 reception, 4 bedrooms, etc. Garden. Available on rent or by purchase; or if single, purchaser could board with widow. Sport of all kinds, and good schools. Offers invited.
4. LONDON, WEST END.—PARTNERSHIP.—A one-fourth or one-third share is for disposal in an old-established good-class non-panel, non-dispensing Practice. Net income of share £1,120. Fees one guinea upwards. Very little midwifery from 31 guineas. Suitable flat available for bachelor, or if married purchaser could choose his own place of residence. Premium for one-fourth share £2,250.
5. PARTNERSHIP.—SOUTH COAST.—In a popular and favourite watering-place, the third share (to commence) of an old-established mixed-class Practice, offering great scope for increase, is for disposal. Cash receipts nearly £1,900 p.a., including panel (increasing) of over 1,150. Visits 3/6 upwards. About 50 cases of midwifery. Eight-roomed house, with garden. Price for freehold £1,450, of which at least £1,000 can be obtained on mortgage. Premium 2 years' purchase.
6. SOUTH OF ENGLAND.—In a pleasant town (pop. 11,000) within 5 miles of favourite watering-place, old-established mixed-class and increasing PRACTICE worth nearly £1,300 last financial year, including transferable appts. and panel of 880. Excellent family residence, standing in its own grounds (tennis court, flower garden, etc.), with ample accommodation. Held at present on lease (2½ years to run) at £90 p.a., and can eventually be bought for £1,700 or less. Premium £2,040, to include drugs, fittings, some furniture, etc.
7. PARTNERSHIP.—SOUTH OF ENGLAND.—The two-fifths share (producing an income of at least £1,500 p.a.) can be acquired by a suitable gentleman in an old-established connection situated in an attractive town near the sea. Appts. and panel held. Visits 5/- upwards, medicine extra. Very little midwifery. Nice house available, held on short lease, but can be purchased. Excellent educational facilities, and sport of all kinds. Premium 2 years' purchase.
8. SOUTH-WEST OF ENGLAND.—PARTNERSHIP.—A one-half share in a very old-established Practice situated in an attractive small town, amidst beautiful surroundings, and within easy reach of the Coast. Gross cash receipts for the past year over £2,900. Panel of 1,218, which, together with appts., brings in about £900 p.a. Moderate expenses. Visits 2/6, plus mileage and medicine 2/6 and 3/6 extra. Very suitable house, with 3 reception, 4 bedrooms, and usual offices. Garden. Price for freehold £750, of which £350 on mortgage. Premium 2 years' purchase.
9. LONDON, WEST.—PARTNERSHIP.—A half share in an old-established mixed general Practice. Average income for the last three years about £4,000. Panel of 3,250. Fees 2/6 to 7/6, visits 3/6 to 10/6, and a few at 21/-. About 30 midwiferies at from 3 to 10 guineas. Convenient house in good position. Held on lease (with no ground rent) with 25 years to run. Price £1,650. Premium £4,000. Must be Scotch or English.
10. CORNISH RIVIERA.—In a small but rapidly growing town (pop. 5,000—6,000) on the Coast, an old-estab. PRACTICE producing last year over £1,000, including appts. and panel of 550 to 600. Opposition weak. Delightful residence, standing in own grounds of 1¾ acres (croquet and tennis lawns, etc.) and eminently suitable for Resident Patients, which Vendor has been in the habit of taking. Contains professional rooms, 4 reception, 9 bedrooms, 2 bathrooms, etc. Water and electric light. Garage. Price for freehold £4,000. Prem. £1,500.
11. LONDON, NORTH.—PARTNERSHIP.—A one-third share, to commence with, in a very old-established mixed general Practice. Income approximately £3,400, including appts. and panel of over 3,000. Surgery fees 2/- upwards, visits 3/- upwards. If unmarried, ingoing Partner could reside with senior; otherwise, suitable house available. Premium 2 years' purchase, half by arrangement.
12. LONDON, SOUTH-WEST.—Within three miles of Charing Cross.—PARTNERSHIP.—A half share, with succession to the whole in about two years, in a very old-established non-panel Practice, held by Vendor 26 years. Steady average income of £2,300. Surgery fees 2/6 and 3/6, visits mainly 5/- and 7/6. Very little midwifery. Good house, in main road, with garden. Held on lease, with nearly 15 years to run, at a rental of only £55 p.a. Premium 2 years' purchase. Very good scope for increase.
13. KENT.—COUNTRY PRACTICE, within six miles of the Coast.—Old-established mixed general Practice. Income for past twelve months £1,672, including appts. about £60, and panel of over 700. Fees 3/6 to 21/-. Not much midwifery 2 to 7 gns. Good house, with 2 reception, 5 bedrooms, etc. Large garden and orchard. Garage for 2 cars. Price for freehold £1,350. Sport of all kinds, and schools within reach. Premium £2,250.
14. PARTNERSHIP.—SOUTH COAST.—In a fashionable watering-place, the two-thirds share is for disposal in a mixed Homœopathic and Allopathic (roughly half and half) good-class non-dispensing, non-panel conection, in which there is a certain amount of surgery, and ingoing partner should be an operating surgeon. Receipts average over £3,600 p.a. Fees up to 10/6. Very little midwifery. Large and suitable maisonette available, with ample accommodation, in excellent position. Garage. Rent, on lease, £250 p.a. Premium for share 1½ years' purchase.
15. PARTNERSHIP.—Within 5 miles North-West of Charing Cross.—The half share of an old-established middle and working-class Practice, averaging about £2,100 p.a., including panel of 1,500. Visits 2/6 to 10/6. House contains, in addition to professional accommodation, 2 reception, 2 bedrooms, bathroom, kitchen, etc. Small garden. Net rental, on lease, about £60 p.a. Premium 2 years' purchase.
16. HAMPSHIRE.—PARTNERSHIP.—Third share of an old-established unopposed Country Practice, in very pretty district within a few miles of a large town, and producing nearly £2,500 p.a., including appointments £130, and panel of 1,520. Visits 5/6 to 21/-. Mids. 2 to 10 gns. Large house (having eight or nine rooms, with garden, etc.), which must be purchased, or ingoing partner could reside in rooms until a smaller one becomes available. Premium 2 years' purchase, half down and balance in 12 or 18 months.
17. KENT.—Old-established Country Practice, situated in very favourite locality within 5 miles of the coast. Income for past 12 months £1,030. Surgery fees 5/6 upwards, visits 5/- to 21/-. Poor Law appt. and panel of about 380. Attractive commodious house, with separate professional rooms. Small garden. Price £1,800. Premium £1,500.
18. HOME COUNTIES.—GROWING COUNTRY DISTRICT.—Old established mainly middle and working-class PRACTICE. Income for the last year £550, with ample scope for increase. Fees 2/6 to 7/6. Little midwifery. Good freehold house, price £1,500, part on mortgage. Sport of all kinds. Knowledge of refractions advantageous. Premium £850.
19. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Long introduction.
20. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.
21. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, and good professional rooms and usual offices. Hot water supply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
22. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good and commodious house, with nice garden. Can be rented on lease at £75 p.a. Garage for 3 cars. Premium 1½ years' purchase, part by instalments.
23. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of about 2,200. Fees 2/6 to 7/6. Midwifery from 3 gns. (about 40 cases yearly). Moderate expenses. Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden. Brick-built garage. Premium £4,500.

REQUIRED.—MEDICAL OFFICER for Cable Company. Salary £500 p.a., all found. Three years' engagement. First-class out and home. Must be of British nationality and under 30 years of age. Sail end of March. Personal application preferred.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

(*Aesculapius*)

PLURIGLANDULAR DISPENSING

The choice of pluriglandular formulæ for the various conditions in which organo-therapy is indicated is often difficult. There may be a considerable difference of opinion as to dosage, and physicians may from their practical experience decide something quite definite but which is probably not in accordance with the usual formulæ.

The growing and varied needs of the profession in this respect are well catered for in our Organo-therapeutic Dispensary. A complete range of Gland substances is always in stock and prescriptions can be promptly and accurately dispensed.

THYMUS CO.

This is one of our recognised formulæ. It is put up in Tablets and in Elixir form, each dose representing Thymus sicc gr. 2, Thyroid sicc gr. 1/8, whole Pituitary sicc gr. 1/10. It is suggested for the treatment of marasmic conditions and atrophy. In addition it may be employed in dealing with nutritional disorders, and defective development of bony or other tissues. Full particulars of this and other formulæ will be found in our brochure "PLURIGLANDULAR FUNCTION," which may be had on application to

Evans' Biological Institute, Runcorn.

GLAXO LABORATORIES

GLAXO HOUSE, LONDON, N.W.1

THE scientific staff of the Glaxo Research Laboratories has amongst its duties to supervise and control the production and packing of all Glaxo, Ostelin, and Maltine lines, so that the Medical Profession may prescribe any of them, confident in the knowledge that the patient will receive an article of the highest possible efficacy and value—be it a matter of bacteriological purity, of chemical constancy, or of vitamin content.

OSTELIN PRODUCTS

"OSTELIN" IN GLYCERIN: 3 minims are equivalent in vitamin D value to one drachm of cod-liver oil.

"OSTELIN" TABLETS: The most suitable form for adults. Valuable in all hypotonic conditions and wasting conditions generally.

"OSTELIN" EMULSION: Contains "Ostelin" equivalent in vitamin D value to 50% cod-liver oil, with calcium glycerophosphate.

OSTOMALT: An unrivalled means of providing vitamins A, B, C, and D.

"OSTELIN" AMPOULES: For intramuscular injection. Each ampoule contains 1 c.c. of a sterile solution of "Ostelin" in olive oil.

ELIXIR "OSTELIN": When diluted 1 to 7 is equal in vitamin D potency to the finest medicinal cod-liver oil.

"OSTELIN" with PARATHYROID TABLETS: The parathyroid constituent controls the distribution of calcium between the blood and the tissues by regulating the proportion of the total serum calcium which is diffusible.

MALTINE PRODUCTS

MALTINE (*PLAIN*): Contains the concentrated elements of wheat and oats in addition to barley, *in the form of a thin syrup*, with a standardised diastatic strength (1000 B.P.C.).

MALTINE WITH COD-LIVER OIL: A perfect emulsion, palatable and easy of assimilation.

MALTO-YERBINE: A stimulating expectorant invaluable in bronchial catarrhal conditions.

MALTINE with CASCARA SAGRADA: Specially valuable in post-natal conditions. Provides the gentle laxative required at this period.

MALTINE WITH CREOSOTE: Indicated in tuberculosis, and in septic conditions of the alimentary canal.

MALTINE WITH PEPSIN AND PANCREATIN: Contains three principal digestants —Diastase, Pepsin, and Pancreatin, in proportions capable of converting all foods into the soluble condition necessary for proper assimilation.

SUNSHINE GLAXO with added vitamin D

Sunshine Glaxo contains the optimum proportion of fat and a quantity of added vitamin D (Ostelin) determined as the result of two years' clinical trials carried out under the direction of physicians specializing in infant dietetics.

The results of the clinical trials of the Sunshine Glaxo in hospitals and in private practice have surpassed expectations. They have shown that the added vitamin D ensures the formation of perfectly calcified bones and teeth, removes any fear of rickets and tetany, and of the general lack of tonicity which has sometimes in the past been observed in bottle-fed infants.

There is one trouble which has been inseparably connected with bottle-feeding; and this is, constipation. Undoubtedly, one definite result that has come from adding vitamin D to the New Glaxo has been—no constipation. The importance of this cannot be emphasized too much.

One of the most interesting features of the clinical reports on New Sunshine Glaxo has been its use for expectant and nursing mothers. Both for the encouragement of breast-feeding and for ensuring a regular, adequate supply of vitamin D to the infant, Sunshine Glaxo is being recommended as part of the daily diet of the mother.

Any request for further information should be directed to Glaxo Laboratories, London, N.W.1

'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready solubility in water. Well tolerated. Absence of local reaction on injection.

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Physicians are invited to write for further particulars and clinical trial samples.

CONSTABLE & Co., Ltd.

announce for publication on April 9th

A NEW WORK by

R. C. WINGFIELD, B.A., M.B.(Oxon), F.R.C.P.

A TEXT-BOOK OF PULMONARY TUBERCULOSIS FOR STUDENTS

Demy 8vo. 417 pages. 52 plates. **31/6** net.

The subject of pulmonary tuberculosis is now receiving such official and general attention that it has become a speciality. Tuberculosis services have been formed, and in one University a Chair of Tuberculosis has been constituted These facts alone justify the publication of a book of this size dealing exclusively with the subject. The majority of the works hitherto published are either too large and detailed for the student, or are too short and elementary. Dr Wingfield has attempted to produce a book in between these two classes in the hope that it will form a complete account of the subject for medical students and practitioners who, during the course of their work, have to pay special attention, either through interest or possibly through a local appointment in town or borough, to the subject of tuberculosis.
This volume is the result of the Author's actual experience combined with his wide knowledge of its literature. It is not, therefore, a conglomerate resumé of other workers' opinions and publications, but a practical, well-balanced, consecutive survey of the disease.

A NEW MEDICAL MONOGRAPH by

H. B. RUSSELL, M.D., M.R.C.P.(Lond.), and C. K. J. HAMILTON, B.M.(Oxon), M.R.C.P.(Lond.).

HEART DISEASE IN CHILDHOOD

Demy 8vo. 104 pages. **7/6** net.

A concise yet complete account of the essentials of heart disease in childhood. The consideration of rheumatism occupies a large portion of this book, as it is now generally recognised that practically all heart trouble in children has its origin in this disease.

AND A SECOND EDITION, REVISED, of

MODERN METHODS OF FEEDING IN INFANCY AND CHILDHOOD.

By DONALD PATERSON, B.A., M.D., M.R.C.P., and J. FOREST SMITH, M.R.C.P.

Demy 8vo. 160 pages. Tables. **7/6** net.

The usefulness of this book has been increased by the inclusion in this new edition of a chapter on diets for sick children and children of school age, a section on stools in infancy, and a description of the common articles of diet with their uses and digestibility.

Descriptive prospectus of these books are obtainable from

BOOKS ON MIDWIFERY

By COMYNS BERKELEY, M.A., M.C., M.D.Cantab., F.R.C.P.Lond., M.R.C.S.Eng.

SEVENTH EDITION. NOW READY.

A Handbook of Midwifery

FOR MIDWIVES, MATERNITY NURSES, AND OBSTETRIC DRESSERS.

This book retains all the text of the last edition with the exception of the chapters on Physiology and the Questions and Answers. The remainder has been thoroughly revised and to a large extent rewritten with the view of further simplifying the subject and of enabling the book to meet more fully the requirements of the practising midwife.

Foolscap 8vo, 588 pp. With Colour Frontispiece and 66 Illustrations in the Text. 8s. net.

NOW READY.

Physiology for Pupil-Midwives

INCLUDING QUESTIONS AND ANSWERS FOUNDED ON THE RULES OF THE C.M.B.

"Physiology for Pupil-Midwives" is a revision of the sections on Physiology and the Questions and Answers which formerly appeared in Berkeley's "Handbook of Midwifery." The incorporation of a new section setting forth the Powers, Responsibilities, Rights, and Opportunities of Midwives makes the book indispensable to all taking up the profession of midwifery.

Foolscap 8vo, 92 pp. Illustrated. 1s. 6d. net.

NINTH EDITION. NOW READY.

MANSON'S TROPICAL DISEASES

Edited by PHILIP H. MANSON-BAHR, D.S.O., M.A., M.D., D.T.M. & H.Cantab., F.R.C.P.Lond.

Every chapter of this medical classic has been thoroughly revised, and many parts of the book have been rewritten. The illustrations have been reinforced by the addition of nine new plates and some thirty new text-figures.

Demy 8vo, 942 pp. 23 Colour and 12 Half-Tone Plates, 401 Illus. in Text, 6 Maps & 34 Charts. 31s. 6d. net.

NEW WORK.

TROPICAL NURSING

By A. L. GREGG, M.A., M.D., M.Ch., D.T.M. & H.Lond.

With a Foreword by the Hon. Sir ARTHUR STANLEY, G.B.E., C.B., M.V.O.

The nursing of the principal tropical diseases is lucidly dealt with, and there is also much practical advice on personal hygiene, food, drink, clothes and kit, etc.

"Contains exactly the information needed about tropical diseases. . . . Vivid, arresting, and comprehensive."—NURSING MIRROR.

Foolscap 8vo, 212 pages. With Illustration in the Text. 6s. net.

SEVENTH EDITION. NOW READY.

ELEMENTS OF SURGICAL DIAGNOSIS

By Sir ALFRED PEARCE GOULD.

Revised by ERIC PEARCE GOULD, M.D., M.Ch.Oxon., F.R.C.S.Eng.

This Manual has been subjected to a careful revision and is now once more abreast of the knowledge upon which the diagnosis of surgical conditions is based.

The increasing rôle played by X-rays in surgical diagnosis is signalized by the addition of several new radiographic plates and appropriate recognition in the text.

Foolscap 8vo, 744 pages. With 26 Radiographic Plates. 12s. 6d. net.

THE ESSENTIALS OF MEDICAL DIAGNOSIS

A Manual for Students and Practitioners

By Sir THOMAS HORDER, Bart., K.C.V.O., M.D., F.R.C.P.Lond., and A. E. GOW, M.D., F.R.C.P.Lond.

This Manual consists of concise descriptions of the methods of investigating cases of disease in the manner actually carried out in practice.

"Well written and thoroughly practical."—BRITISH MEDICAL JOURNAL.

Crown 8vo, 702 pp. 8 Colour and 11 Black-and-White Plates, and Figures and Charts in Text. 16s. net.

EIGHTH EDITION.

CLINICAL METHODS

By ROBERT HUTCHISON, M.D.Edin., F.R.C.P.Lond., & HARRY RAINY, M.D., F.R.C.P.Edin., F.R.S.E.

Revised by ROBERT HUTCHISON.

"In 646 pages of text and some 40 pages of index are to be found the most remarkable summary extant of all that is best as regards the examination of patients."—LANCET.

Foolscap 8vo, 690 pages. With 17 Colour Plates and 150 Illustrations in the Text. 12s. 6d. net

CASSELL & CO., LTD., LA BELLE SAUVAGE, LONDON, E.C.4.

When Operation for Hernia is Inadvisable—

a Spencer Abdominal Belt, or Supporting Corset Gives Excellent Results.

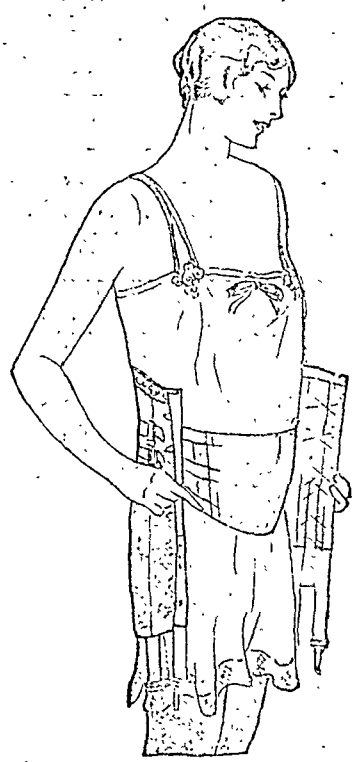
TO be effective a support for hernia must stay in place. Each Spencer support is designed especially to meet the needs of the individual who will wear it. This assures *perfect fit and adjustment at all* times, since the Spencer support for hernia is non-elastic as well as individually designed.

Spencer hernia supports are comfortable. They fit, and they have no hard rubber or heavy *metal parts.*

They are also strong and well made, in order to provide both durability and absolute security for the patient.

Spencer supports for reducible umbilical hernia may be prescribed with or without auxiliary pads, according to the patient's need.

For cases of non-reducible umbilical hernia, a special protecting pad used with a Spencer Belt will shield a small hernia of this type from injury, and will prevent increase in the size of the hernia mass. For a very large non-reducible umbilical hernia, the Spencer Belt is made so that the mass is gently but firmly supported, to provide comfort and to guard against increase in the size of the hernia. *Inguinal hernia, ventral hernia* at the site of an operation scar, can be properly taken care of by a Spencer support.



Spencer Supporting Corset.

Front unclasped and held back to show the inner supporting section.

The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your *supervision.*

We issue the following booklets on the use of Spencer Supports: Hernia, Sacro-iliac Strain, Enteroptosis and Intestinal Stasis, Movable Kidney, Pregnancy and Post-*partum* Support. We will gladly send you any of them in which you are interested.

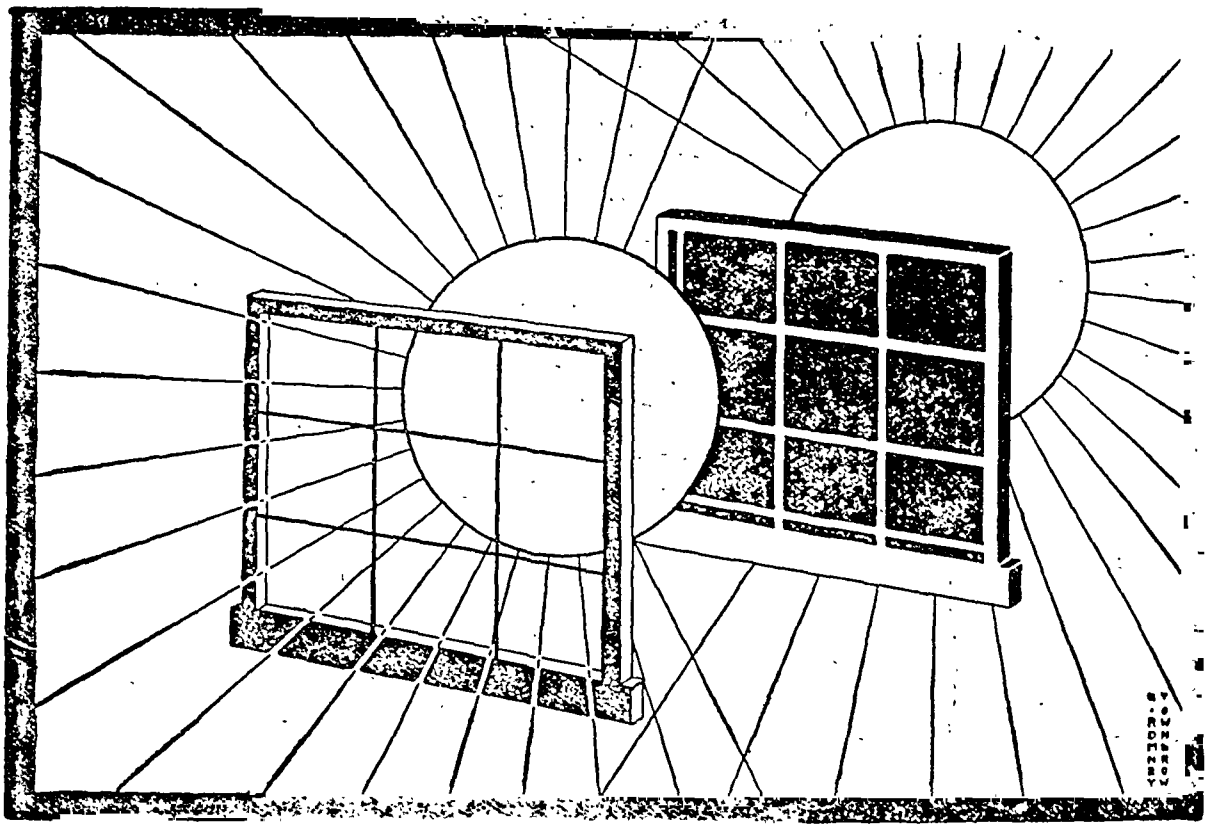
Kodak Limited (Medical Dept.)
Kingsway, London, W.C.2.



A GENTLE RESTORATIVE IN CONVALESCENCE

"Vita" Glass is a practical measure to prescribe for patients Installed at a moderate cost

At one time the medical practitioner had some hesitation in suggesting the "Vita" Glass window to his patients because of the considerable expense involved, but nowadays, enough "Vita" Glass for an average sized bay window in a modern house costs about 38/- plus the cost of fixing.

By allowing free passage to the active ultra-violet rays "Vita" Glass assists in the recovery of patients who cannot be taken outdoors with safety owing to the risk of cold winds and sudden changes in temperature. It provides a gentle stimulation which is of the utmost value during convalescence.

An account of the ample demonstration that "Vita" Glass has given of its power to transmit ultra-violet light will be forwarded to any interested medical man. Write to the "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C. 2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

health through your windows

"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens

V. 154

Ultra-Violet Ray Therapy has come to stay!

"An enormous amount of work has been done on ultra-violet ray therapy, both in this country and abroad, and numerous publications on the subject have appeared.

The clinical results have been sufficiently numerous and striking to justify the conclusion that this particular form of treatment has come to stay. Its value is becoming more widely appreciated, and the sphere of its usefulness better defined.

On the whole the results are most encouraging. They fully justify the expense and labour involved in providing this method of treatment."

BOOTS PRODUCTS

"VITAMALT"

Regd

RICH IN ESSENTIAL VITAMINS A, B, C, & D.

Vitamins have gone beyond the experimental stage. Modern research work has demonstrated the vital necessity for the various vitamins against anti-infective processes, rachitic conditions, and deficiency diseases, and in providing for the human system a very necessary adjunct in the maintenance of good health. Vitamalt is the only preparation of its kind which is guaranteed to contain vitamins A, B1, B2, C, and D, and it has been demonstrated that Vitamalt assists the metabolic processes, promoting normal development of bone and tissue, and ensuring correct assimilation of calcium. In Vitamalt, vitamins are incorporated in the proportion which science has indicated as the most suitable for average conditions.

Price 1/9 and 3/= per jar.

Local Anæsthesia in Surgical Practice

FRACTURE OF THE RIGHT FEMUR.

Typical Case.

Mrs. S. E. B., aged 71 years.
Diagnosis: Supracondyloid T-fracture of the right femur.
Operation: Incision, reduction, and application of screws.
Anæsthesia: Transverse infiltration block.

Technique of Anæsthesia: Infiltration block, Novocain-Adrenaline 180 c.c. The patient was given no preliminary hypodermic medication. She was placed on the extension apparatus, great care being taken to make her as comfortable as possible. She was held in position by applying the extension screws, and the skin was prepared by painting with iodine. The line of incision—25 cm. in length—was infiltrated, each excursion of the needle bringing its point in contact with the femur. An especially large deposit of solution was made just posterior to the bone in the region of the fracture. The bone was exposed and the fragments gently separated by the use of a scalpel and chisel. In the meantime the traction screws were brought into play, and the lower fragments were gradually brought down to the proper level. One long screw and a stove-bolt were introduced, after drilling the bones, in order to prevent a recurrence of the displacement after operation, the fractured surface being rather oblique. This patient left the table with a pulse of 80. There was no hæmorrhage, no shock, no pain, and she presented no post-operative complications.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

In Convalescence

For combating the debilitating effects which often follow a serious illness the physician prescribes Radio-Malt, the ideal extra-dietary product for those suffering from post-influenzal debility and similar after-effects of serious illness.

Radio-Malt contains Vitamins A, B_1, B_2 and D in scientifically-standardised quantities; it possesses great power to repair wasted tissue, it stimulates the appetite, promotes the proper assimilation of food and thus increases the patient's rate of recovery.

In addition, Radio-Malt is definitely anti-infective; also it promotes healthy growth and corrects faulty calcium metabolism. It is valuable also to the mother during both the pre-natal and the nursing periods.

Radio-Malt possesses a delicious flavour, and the fact that it is so readily digested makes it particularly suitable for invalids.

Radio-Malt is issued in glass jars of three sizes, and is sold by all pharmacists.

CATARRH

Its Prevention and Relief

Mistol, applied with a Mistol Dropper in the nose, is extensively prescribed by nose and throat specialists to prevent the recurring attacks of catarrh, and also to aid in the relief of acute paroxysms resulting from this ailment. Being an oily preparation, Mistol diffuses and spreads itself in a thin film over all parts of the mucous membranes of the nose and throat. It clings tenaciously to mucous membranes, and is not easily washed away by the natural secretions. Thus it affords relief in all inflamed and irritated conditions, and assists in warding off infection.

Sold in original sealed cartons containing a—

B

TOXINS
and
Arterio-Sclerosis

The great change that has been brought about in the treatment of arterio-sclerosis and certain other circulatory diseases through the widespread conviction that—as pointed out by Bishop*—

"The vast majority of cases as they occur in adult life are due to the indirect influence of intestinal putrefaction upon the blood vessels and nervous tissue"

is of more than passing interest to the medical practitioner, now that we have a really efficient non-toxic intestinal bactericide that can be administered with the certainty that it will not only destroy the causal agents of the putrefaction referred to by Bishop, but will do so without absorption or toxic action.

N. Y. Medical Journal, September 9th, 1911.

The efficiency of Dimol in the treatment of *many other intestinal conditions of bacterial origin* is conclusively told in the interesting clinical reports, which, together with a brochure dealing with the pathological significance of the intestinal toxaemias, will be sent to any physician on application to the

Dimol Laboratories, Limited, 40, Ludgate Hill, London, E.C.4.

ACIDOPHILUS BACILLUS IN A NEW FORM
M-A-B

MULFORD ACIDOPHILUS BACILLUS BLOCKS are a concentrated, mass culture of the Lactobacillus Acidophilus, incorporated in agar jelly and protected with a chocolate coating.

MULFORD ACIDOPHILUS BACILLUS BLOCKS, M-A-B, are used for the establishment of Acidophilus Bacillus in the intestines, supplanting the putrefactive bacteria, which flourishes under modern diet, and restoring a normal bacterial condition approximating that of early childhood.

ADVANTAGES.

Concentrated cultures of *living* Acidophilus Bacilli, each block containing 150 billion organisms at time of issue.

The required large dosage in small volume.

An effective vehicle for carrying the bacilli to the lower bowel where they supplant the objectionable bacteria.

The most convenient, attractive, palatable, and economical way of taking the Acidophilus treatment.

Effective—yet entirely free from laxatives, cathartics, or drugs of any kind.

A full-sized trial package and Literature sent free to any member of the Medical Profession.

Therapeusis in Pulmonary Tuberculosis

By increasing the calcium content of the blood the resistance of the whole organism against the bacterial toxins is greatly strengthened, there is a decrease in the excitability of the nerves, and a definite improvement in the functions of the alimentary canal, due to the combined anti-toxic and astringent effect of the calcium salts.

Successful calcium therapy depends upon calcium retention. The calcium-sodium-lactate compound, presented as a double salt in the form of Kalzana is easily absorbed and well retained. The sodium-lactate is changed within the body to sodium-carbonate, which raises the blood alkalinity to the extent necessary to secure calcium retention.

"The Practitioner," June, 1924, says:

"It is indicated in all conditions in which a lime food is required, particularly because Kalzana promotes calcium retention."

Kalzana is in daily use at over 200 British Sanatoria and Hospitals.

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

THE LIME FOOD

Made by A. WULFING & CO., Amsterdam, Holland.

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available at 15/- per 1,000 tablets. Adequate samples for clinical trial sent with pleasure upon request.

Wulfing

Bowel Inertia

THE Physician is familiar with the patient who complains of headache, loss of appetite, depression, who is not suffering pain but is nevertheless conscious that his or her general health is far below the standard it should be.

Diagnosis often reveals auto-intoxication—the result of habitual constipation. The use of a suitable eliminant is indicated.

"Cristolax" proves exceptionally successful in such cases. It is composed of 50% of the purest medicinal paraffin in combination with 50% "Wander" Dry Malt Extract. The high diastasic quality of the pure malt extract gives material assistance to the digestive process which is often impaired in this condition, whilst the oil content lubricates the intestinal tract, keeps the fæces soft, and ensures their complete expulsion.

A delicious preparation in a clean, convenient dry form for infants, children, and adults.

JB 93

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

PLASMONA

THE BLOOD & NERVE FOOD

is the sovereign **RESTORATIVE** and **NERVE TONIC** in convalescence, general debility and exhaustion, and during physical and mental overstrain.

PLASMONA

is very simply prepared

by mixing one large heaped teaspoonful to a paste with a little **cold** water, then adding a quarter to a half cupful of **cold** water or, preferably, milk.

Hot liquids must not be added

as the heat, besides affecting the flavour, would partially destroy the valuable vitamin content so carefully preserved during manufacture by the use of the latest vacuum plant.

CLINICAL SAMPLES ON REQUEST.

Artificial Teeth and Dental Plates must be kept Sanitary!

There is

KOLYNOS

DENTURE POWDER

A safe and sure cleaning agent which will not injure the most delicate dental plate.

Samples on application to

THE KOLYNOS LABORATORIES, CHENIES STREET, LONDON, W.C.1.

The New Concentrated Antitoxin

Important discoveries by eminent immunologists enable The British Drug Houses Limited to offer to members of the medical profession an anti-diphtheritic serum possessing the following properties unique in the history of diphtheria immunisation:—

Concentration of 2,500 units per c.c.
Protein content of less than 10%
Maximum reaction velocity unimpaired

This antitoxin is known as

DIPHTHERIA ANTITOXIN D.S.I. BRAND

(Concentrated and Refined)

The advantages of such remarkably high concentration combined with an unprecedented low protein content without loss of reaction velocity are obvious. Such advantages reduce to a minimum the risks usually associated with inoculation.

Diphtheria Antitoxin D.S.I. Brand (Concentrated and Refined) is now available and is issued as follows:

Super-concentrated and Refined—2,500 units per c.c.
Rubber-capped vials of 4 c.c. containing 10,000 units
" " 8 c.c. " 20,000 "

Concentrated and Refined—1,500 units per c.c.
Sealed ampoules of 1 c.c. containing 1,500 units
" 2 c.c. " 3,000 "
Rubber-capped vials containing 4,000 units
" " " 8,000 "
" " " 10,000 "

Alternative Methods in the

TREATMENT OF BOILS CARBUNCLES & FURUNCULOSIS

Antivirus

The latest method, which has proved so useful with patients who object to injections, consists of local treatment with Staphylococcus Antivirus. Reports from hospitals and Skin Specialists state that this Antivirus is as efficient or more efficient than subcutaneous inoculations with Vaccine.

Detoxicated Vaccine

Practitioners who prefer the more orthodox forms of treatment are recommended to use Detoxicated Staphylococcal Vaccine; its special feature is the production of great immunity with little or no reaction. This is achieved by removing all the toxic elements of the germ during the preparation of the Vaccine. Doses up to 50,000 millions are given without malaise.

Ordinary Vaccine

To meet the requirements of those who consider that a slight reaction has definite therapeutic value Ordinary Staphylococcal Vaccine is available. It has proved generally successful and is very inexpensive.

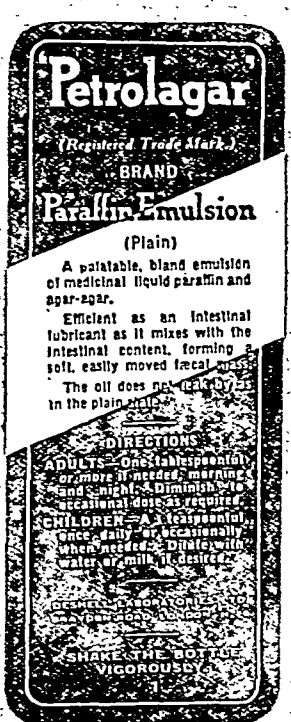
'Petrolagar'

REGISTERED TRADE MARK



FOR
BED PATIENTS.

Bed patients are hardly fit subjects for the old-fashioned drastic purge, yet regular bowel motion must be maintained.

Prescribe "Petrolagar" Emulsion—it has so many advantages at this particular time.

"Petrolagar" Emulsion provides ease and comfort for your patients by giving them a natural bowel motion with no irritation whatsoever.

Write for literature and specimens of the new bottle to:

Deshell Laboratories Ltd.,
Braydon Rd., London, N.16.

Anaemia and Debility

A low red-blood cell count can be produced by the insidious auto-intoxication of bowel origin, as well as by the more obvious causes—haemorrhage, prolonged fever, chronic septic infection, wasting diseases, etc.

A vicious circle is formed, the toxaemia from the bowel impoverishing the blood, which in turn leads to impaired function of the intestinal muscle and more stagnation and toxaemia results.

The general debility accompanying anaemia leads to inactivity, which again encourages constipation.

Andrews Liver Salt breaks the vicious circle by removing the products of intestinal stasis, purifying the blood and promoting a sense of well-being and energy.

Before prescribing iron, a course of Andrews, the antacid effervescing saline, will be found beneficial.

Dose: ½-3 *teaspoonfuls in a glass of water.*

N.B. *A large size tin will be sent free on request to any member of the medical profession.*

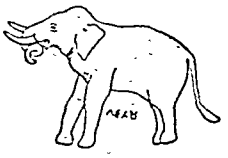
BOMBAY SHANGHAI BUENOS AIRES



EDICT OF ASOKA, IN WHICH HE EXPRESSES HIS ABHORRENCE OF WAR AND PROCLAIMS HIS IDEAL OF TRUE CONQUEST.—In this edict, which may still be seen carved upon rocks in India, Asoka set before his people new ideals in statesmanship: "The Kalingas were conquered when His Sacred and Gracious Majesty the King had been consecrated eight years. One hundred and fifty thousand persons were thence carried away captive, one hundred thousand were there slain, and many times that number died. . . . . That is a matter of profound sorrow and regret to His Sacred Majesty. . . . . If a hundredth part or the thousandth part were now to suffer the same fate, it would be a matter of regret to His Sacred Majesty. Moreover, should anyone do him wrong, that, too, must be borne with by His Sacred Majesty, so far as it can possibly be borne with. Even upon the forest folk in his dominions His Sacred Majesty looks kindly, and he seeks to make them think aright, for otherwise repentance would come upon His Sacred Majesty, . . . because he desires for all animate beings security, self-control, peace of mind and joyousness."

PUBLIC NOTICE

re

"RYVITA CRISPBREAD"

and

"THE RYVITA CRISPBREAD HABIT"

We acknowledge with much pleasure and grateful thanks the volume of congratulations on our successful introduction of "Ryvita Crispbread" to the British Isles.

When we gave to the British public this new and invaluable food—creating throughout our country *the Ryvita Crispbread habit*—we started what has now become almost a revolution in the bread-eating habit of the nation.

"Ryvita Crispbread" is the successful outcome of generations of experience directed to making just this one thing *right*.

That it is, and does, all that we claim for it is proved by the welcome it has received from Doctors, Dentists, and food experts, who not *only prescribe it but have it as the daily bread* in their own homes.

Because of its success, not only with the professions and the experts, but with the ordinary folk of these islands, there have arisen a number of "imitation Crispbreads." Some of these are not bad—*as imitations*—some are bad, some quite bad.

We make "Ryvita Crispbread" in Sweden because this type of bread is essentially and characteristically Swedish. The special ovens which we use are a mere item compared with the skill and long experience needed to make Ryvita *right*. It has taken generations of experience devoted exclusively to making just this type of bread to win the present perfection of "Ryvita Crispbread."

Although we make "Ryvita Crispbread" in Sweden, we who own and control the Ryvita Company are British. We buy British when it is best. But, like most other British people, we *will* have the best.

When we smoke a cigar it must be—Havana made in Cuba. After dinner, when we offer our friends a glass of port—it must be port from Portugal. When we have a little party, our champagne must be genuine from France. The suggestion that you should buy imitation Crispbreads merely because they are "British made" is as ludicrous as it would be to claim pre-eminence for British Cigars—British Port—or British Champagne.

Whilst the Ryvita Company is proud of its achievement in popularising the healthful *Ryvita Crispbread habit* in this country, it entirely dissociates itself from these hastily prepared substitutes.

The genuine original "Ryvita Crispbread"—crisp, scrunchy, and delicious . . . . the bread of life and health—*helps to make* indigestion, constipation, malnutrition, and obesity unknown.

"Ryvita Crispbread" is sold by all good grocers and stores at 1/6 per 40-50 slice (1 lb.) carton; ½ lb. carton, 10d.

THE RYVITA COMPANY

412, RYVITA HOUSE

96, SOUTHWARK STREET

"RYVITA CRISPBREAD MAKES YOU FIT—AND KEEPS YOU SLIM"

A Lecture
ON
THE DEBILITATED CHILD.*

BY
C. WILFRED VINING, M.D., F.R.C.P.,
ESSOR OF CHILDREN'S DISEASES, LEEDS UNIVERSITY; PHYSICIAN TO THE CHILDREN'S DEPARTMENT, GENERAL INFIRMARY, LEEDS.

are living at a time when prevention of disease and recognition of its earliest signs are being called for no uncertain voice, and those of us who are specially gaged in work amongst children realize only too well difficulties met with in the understanding and interstation of defects in health at an age period when one uld expect the problem to be in its simplest form.

The system in vogue in this country, while it offers erty of the subject and free choice of doctor, has the advantage that it leaves the decision as to whether the ild needs medical attention to the parent rather than to e expert. No doubt the development of the school edical service will do a great deal to remedy this. any abnormalities which we, as experts, recognize as idence of health defect, possibly of a serious nature, are oked upon by parents as part of the natural development the child. Pains in the legs are growing pains, nervous nditions are due to worms, refusal to gain weight proves at the child is wiry and following in his father's footeps, or the child's C3 condition is accepted as evidence a delicate constitution inherited from the mother's side.

I have met with some twenty children with established quired heart disease who had not at any time been der medical treatment. In none of these children had ere been a history of chorea or joint rheumatism, and five of them the most detailed inquiry failed to elicit om the parent evidence of any health disturbance whatever. Personally I refuse to believe that a child can quire valvular disease without there having been some gree of health disturbance during its development. As e who has worked in a large out-patient department for me fifteen years, during eight of which my patients have en children, nothing has impressed me more than the rge number of children who are brought with health fects which are accompanied by no gross physical signs, t whose disabilities are more or less serious, frequently ronic, and most baffling in their refusal to respond to y treatment we can offer in hospital practice.

I have deliberately chosen the title "The debilitated ild" in order to allow myself freedom to discuss the bject from any point of view. I prefer not to use the rd "delicate" because this infers congenital weakness. hile a certain minority of these children are undoubtedly e victims of a bad start in life, I am convinced that e majority acquire ill health for reasons and from causes hich I propose to touch upon in this lecture.

The debilitated child is brought to us for many reasons, d his health abnormalities can be viewed from different gles. The majority of these children are found among e hospital class, though by no means an inconsiderable inority are found amongst the children of the well-to-do. am going to deal with the age period 3 to 12 years—most the cases range between 5 and 10 years—and I can best velop my subject by giving a list of the symptoms presnted by these children and noticed during periods of bservation varying from a few months to several years.

The first perfectly just criticism will be that I am inching together a number of entirely different conditons. My answer is that I am merely stating the actual mptoms of a large group of children whose histories peat themselves with monotonous frequency, and whose ppearance, behaviour, and physical condition seem to dicate that they have some features in common which make it desirable that they should be studied, at least in the first instance, as a group. Can we make any kind of order out of this seeming confusion?

Analysis of the Symptoms of the Debilitated Child.

Numerical frequency of symptoms presented by (A) 300 debilitated children, compared with relative frequency of the symptoms in four arbitrary subgroups—namely: (B) 121 toxic debility or rheumatic type cases, (C) 61 supposed tuberculous cases, (D) 55 cases of "chronic intestinal dyspepsia," and (E) 63 "nervous" children.

	A.	B.	C.	D.	E.
Nervousness	203	68	38	39	63
Loss of appetite	237	86	44	48	42
Wasting or "no gain"	203	74	47	37	45
Tired feelings	164	67	38	30	29
Pallor or "faints"	152	54	30	33	35
Disturbed sleep	147	60	24	26	37
Constipation	145	56	26	31	29
Limb pains	120	58	23	20	29
Headaches	107	49	20	18	20
Threadworms	97	29	20	29	19
Abdominal pain	91	32	15	25	19
Habit spasm	59	16	5	7	31
Bilious attacks	51	22	7	15	7
"Sweating"	50	13	22	9	9
Nocturnal enuresis	48	9	7	9	21
Sore throats	41	27	6	3	5
"Swollen glands"	37	21	6	5	5
Loose stools	33	7	7	12	7
Latent chorea	29	13	2	0	12
Pain in the side	28	12	8	5	3
Depraved appetite	21	8	5	5	3

Without for the moment committing ourselves to an opinion as to the production of these symptoms, we can at least view them as belonging to three main groups: (1) those related to the digestive system and intestinal tract, in which group we would place abdominal pain, constipation, and loss of appetite; (2) those suggesting the presence of a toxaemia—for example, aching limbs, tired feelings, listlessness, and headaches; and (3) those related to disturbances of the nervous structures—namely, nervous irritability, fidgety states, habit spasm, disturbed sleep, nocturnal enuresis, and nervous unrest generally. The children frequently seem to classify themselves in this way, certain symptoms being so prominent that we label this child as an example of *chronic intestinal dyspepsia* (or, as Reginald Miller[1] has designated him, the "intestinal child"); another child, with aching limbs, tired feelings, and want of energy, pointing to the presence of toxaemia, we may label as "toxic debility" or the "rheumatic type"; while a third child we may label "nervous" because of the prominence of the nervous manifestations. The symptoms of another child may suggest the possibility of tubercle, in that wasting, cough, catarrhal bronchial tubes, and sweating are prominent in the history obtained from the parent. I want, however, to make it quite clear that any such grouping of symptoms and children is arbitrary, and is carried out merely to call attention to certain types which present themselves at the clinic. Too much pigeon-holing and classification may lead to failure to appreciate the main underlying defects. We find that nervousness of some degree is common to all groups, that loss of appetite is found as frequently in other groups as it is in the child classified as "intestinal," and that constipation, loss of weight, and sweating are to be found distributed among all types. In order to show this I have compared the four subgroups with the main group as a whole.

The clinical examination also reveals certain physical characteristics which are more or less common to all the

* Abstract of a British Medical Association Lecture delivered to Darlington Division.

groups. The children are underweight, pale, sometimes sallow, and many have dark rings under their eyes. They are usually fidgety, and some show habit spasm, and generally they give the impression of being timid and apprehensive. Their muscular systems are toneless and poorly developed, and this tends to produce stooping and general "flop," which results in an exaggeration of the natural curves of the spine and prominence of the abdomen. In a proportion of the children the abdomen actually is slightly distended. The glands in both triangles of the neck are more easily felt than in a healthy child, and this is specially true of the glands of the posterior triangles. This is not merely a local enlargement, as the axillary glands are nearly always felt to a degree unusual in the healthy child, and sometimes the hyperplasia is very evident. The tonsils are frequently enlarged and sometimes unhealthy in appearance; evidence of adenoids is not uncommon. Needless to say, the degree of physical defect varies from case to case, and in many the degree of physical debility has not reached a stage recognizable by the parent, who may assure us that the child was perfectly well until a week or two previously, when a particular symptom manifested itself.

The Explanation of the Symptoms.

What explanation can be offered for these symptoms? In discussing this I must refer to the subject of diathesis, which has been revived during recent years. The expressions lymphatic, exudative, nervous, rheumatic, and tuberculous have been used from time to time. I doubt whether they have done more than to make confusion worse confounded.

Dr. H. C. Cameron[2] has suggested the division of children into two main groups—namely, the exudative diathesis group, which includes the old scrofula type, and the neuro-arthritic group. He believes that the two types are the result of inherited constitutional peculiarities which make the child react differently to abnormalities of his environment. Cameron regards catarrhal affections generally, glandular enlargements, and the tendency to rheumatic and tuberculous affections as characteristic of the former group, and nervous upsets, cyclical vomiting, vasomotor disturbances, and lack of energy as characteristic of the latter group. My own feeling is that the insistence upon a diathesis as an explanation for the way in which the child responds to infection and environmental stimuli is not without value in some cases, but I doubt whether it is possible in the majority of children to make any such differentiation. I fancy it is better to accept each case on its merits rather than endeavour to judge it in the light of a preconceived theory of diathesis, although it must be confessed that Cameron's "nervous child," with his special liability to metabolic upsets, is very true to life.

The Nervous Child.

Though no one explanation adequately covers all cases, certain facts and probabilities may be admitted. Nervousness is of two main types. There is the unrestrained and more positive type, in which the nervousness is more active and insistent; the children of this type are highly strung, emotional, restless, and mentally alert, though lacking the ability to concentrate; they are specially prone to habit spasm, so-called latent chorea described by Reginald Miller,[3] tired feelings, aching limbs, nocturnal enuresis, bilious attacks, and headaches. In the second and, in my opinion, more common type the child is characterized by irritability of temper, fretfulness, and timidity. I would, however, again emphasize the point that there is no clear line of distinction, the majority of our cases presenting nervous symptoms in all kinds of groupings and in combination with other abnormalities in a way that makes it hopeless to attempt classification. There is, however, no doubt that only in a minority of these children is there an inherited nervous instability, but while symptoms such as habit spasm, bed-wetting, and night terrors may occur in children who by no stretch of the imagination could be called debilitated, it is when the child with the inherited instability become debilitated that these symptoms are acutely developed. But taking nervousness generally, I would say that the large majority of nervous children acquire their nervous instability during life, and that it is among debilitated children that the majority of the nervous cases are to be found.

The Causes of Acquired Nervous Instability.

While agreeing that the environment, in which I have included parental care, bad hygiene, and excessive psychical and physical stimulation, will accentuate the condition, it is my belief that the two chief factors producing nervousness are chronic toxaemias and deficiencies in the diet. The deficiency is usually not in total calories—the debilitated children are not starved children in the true sense of the word—but a relative deficiency in one or more essential constituents, which, acting over a prolonged period, gradually brings about debility and damage of the more delicate nervous structures of the growing child. I have myself pointed out that many of the symptoms of these debilitated children can be legitimately grouped under the heading of rheumatic toxaemia. All authorities are agreed that nervous instability forms an important part of the rheumatic picture, and the question at issue would therefore appear to be this: Is the nervous instability evidence of an inherited diathesis favourable to the development of the rheumatic affection, or of an acquired health defect which may precede by months or years the full development of rheumatism?

The presence of toxaemia is difficult to prove or disprove, but it is not unreasonable to believe that many of these nervous phenomena are caused by toxic irritation. The toxic state may be bacterial or metabolic in origin. Cameron,[5] and recently Osman,[6] have suggested that the cause of many of the nervous phenomena is an acidosis or ketosis, and recommend as treatment the free use of sugar and the reduction of fat in the diet. We find acidosis not infrequently amongst children whose parents are endeavouring to ensure against tuberculosis by forcing on them milk foods and cream, and acidosis may also occur in the child whose diet does not contain excess of fat, the explanation then being that the child possesses an inherited unstable metabolism and a nervous system which are easily influenced by environmental and toxaemic stimuli.

My criticism of this explanation would be this: While agreeing that the immediate states of acidosis can be met by increasing the sugar ration, I would hesitate to believe that the prevention and cure of the debilitated state of which its acidosis exists in the free use of easily assimilated carbohydrate. In the first place, the majority of these children get little but carbohydrate. Though their diet may be short in total calories it is certainly not relatively short in carbohydrate calories. A starvation diet may result in acidosis, and the child with a lost appetite may get his acidosis in this way, but this is merely a vicious circle which may be broken temporarily by the addition of sugar. The prevention and cure of the underlying condition which has led to the formation of the vicious circle is a very different problem. In the second place, acidosis is far more frequently the result of a toxaemia than it is a primary condition, and if we concentrate our attention upon the acidosis we may miss its underlying cause. I have no doubt that Dr. Cameron and Dr. Osman would be the last to insist that carbohydrate is the most important constituent of the child's diet, and any criticism I have put forward is offered rather to emphasize the importance of the other constituents of the diet, specially of the proteids, which of late have been relegated to a less important position than they deserve.

The throat and the alimentary tract suggest themselves as the two important points from which toxaemias may arise. The time has not yet come to define accurately the relationship of unhealthy conditions of the nasopharynx to the debilitated state; it will require a wide statistical survey over a considerable number of years before the final verdict can be given. The problem is, however, of such importance that I am bound to consider it.

Abnormalities of the nasopharynx are not confined to children of the hospital class, but I know of no figures

t give the relative incidence between one class and ier. Such statistics would possibly help in deciding actors at work causing enlargement of tonsils and ids. There are many who would estimate the impor- of the abnormalities of the nasopharynx in this way. rgement of tonsils and adenoids is common to all s. The cause of the enlargement is repeated infec- , to which all are prone. Among those children who lso debilitated or whose environment is defective such ion to infection is likely to result in a greater degree nhealthiness of the nasopharynx, and it is likely that rption of organisms and their toxins will take place readily. Hence the more frequent development of otoms due to septic absorption amongst these children. as been stated that the reason why Eton boys are free rheumatic infection is because 70 per cent. of them had their tonsils and adenoids removed before joining school. During 1922 Kaiser[7] reported from America result of the operation upon the weights of a series of 0 children between the ages of 3 and 15 years. He es:

"They were all urgent cases and presented themselves for opera- because of throat symptoms, and not because of malnutrition. compared with similar children 7 per cent. were overweight, er cent. were of average weight, and 34 per cent. were under- ght. After periods of six to nine months the percentages of e three weight groups were changed so that 50 per cent. of underweight group had attained normal weight."

Obviously diseased tonsils and adenoids do not necessily impair nutrition, but the improvement in the underght group after their removal suggests that they may so. Recently Paterson and Bray[8] in this country have wn that in selected cases removal of nasopharyngeal ection was followed by increase of weight and the aring up of numerous constitutional symptoms, apart om any improvement in the local condition.

I would, however, remind you that there are other sides the problem which require to be set off against these dings and opinions. In the first place, the numerous sturbances and symptoms which may appear in conjuncon with the unhealthy nasopharynx do frequently occur children whose throats show no abnormalities and whose ands at the angle of the jaw are not enlarged. The eumatic affection, including heart lesions, occurs in ildren whose throats have been thoroughly cleared. It not uncommon to find that certain symptoms, such as uresis or bilious attacks, cease immediately after the eration, only to recur again after some months. This in keeping with the peculiar way in which these symtoms will occur for a time in connexion with all kinds psychological stimuli, and certainly one could instance ases in which enuresis started for the first time after the peration; indeed, I need hardly remind you that this peration performed upon a nervous child sometimes accenuates the nervous condition in a most distressing way. would also point to the frequency with which aural disharge follows the operation and to the by no means nfrequent development of enlargement of the cervical lands during the months or years which follow. These nfortunate happenings, and the fact that acute heumatism, and especially chorea, occasionally follow in he wake of the operation, may, of course, be attributed to he stirring up of a germ nest, with resulting dissemina- ion into the local structures or the system generally, and t could be said that the eradication of the germ nest was he lesser of two evils, notwithstanding the results which ollowed. But here again it should be mentioned that cute rheumatic chorea, which all agree is a streptococcal ncephalitis, may undoubtedly follow a shock of any type.

J. H. P. Paton[9] has recently compared children who ave had the operation performed with children who have ot. Both groups of children belong to the professional nd well-to-do class and are pupils attending a large oarding school. He writes:

"It is evident that those subjected to the operation were not nly no better than the rest, but were actually worse in practically every particular with the exception of enlarged cervical lands."

My own personal impressions have been that when the local condition of the throat is obviously unhealthy and the nasopharynx is obstructed, the operation, besides remedying the local condition, does undoubtedly produce good and often striking results in the child's general health. These results, however, are often only temporary, and the symptoms not infrequently return after a few months. I have also seen children whose debilitated state seems to date from the removal of their tonsils and adenoids, and a recent review of cases has increased my belief that the routine removal of the tonsils and adenoids of debilitated children is a mistake and should only be undertaken after a thorough review of the child's condition. I have figures which refer to 100 children who have had their tonsils and adenoids removed and 200 children who have not; both groups belong to the poorer classes of the community, and all of them come under the broad classification of debilitated children. These children have been watched for periods ranging from six months to three years, and the figures relating to the tonsillectomized group only deal with the post-operation period. I find that for each six months period the "*no operation*" group shows an average greater gain of weight than the "operation" group.

Of the 100 tonsillectomized children 23 had had the operation performed previous to their first attendance at my clinic, and in only 29 other cases was it possible to compare the weight gains before and after the operation. In the six months after operation 12 showed a greater gain, 14 showed a lesser gain, and 3 showed an equal gain in weight. Comparing periods of twelve months before and after the operation, 3 showed a greater gain in the year following operation, 7 showed a lesser gain, and 1 showed an equal gain.

A legitimate criticism of my figures would be that the children who ceased to attend after operation would quite likely be those who had so improved in health that further attendance was deemed unnecessary by the parent. I can only say that in a small minority who were looked up and prevailed upon to return for examination the gain in weight did not encourage me to believe that failure to attend was due to return of health. In my opinion the benefits derived from this operation have some relation to the chances of convalescence afterwards, to the type of home to which the child returns, to the state of the child's nutrition at the time, and, lastly, to the efficiency of the mother. This also may be said: anything short of complete enucleation is useless, and should be discouraged. The operation should not be undertaken in cases where the local condition does not warrant it merely on the off-chance that the child's health defect may be improved.

While discussing the influence of the toxaemias the question of tuberculosis must be mentioned. Many of these children are labelled as tuberculous or pre-tuberculous. Some 50 per cent. of them give a positive skin reaction to tuberculin, but I am confident that their debility and their symptoms are not due to tuberculous disease. Watched over a period of years they do not behave like tuberculous cases, and they do not blossom out into frank cases of tuberculosis during adolescence. The age period I am dealing with is particularly free from mortality from tuberculosis, and while risking the criticism of dogmatism I would say that frank tuberculosis arising during adolescence is usually a fresh infection developed from contact with another individual with the disease.

It may very naturally be suggested that a local gland lesion might be sufficient to produce a debilitating influence and toxaemia. This I would very much doubt, as in my experience purely local disease, when obviously present, does not produce either debility or the kind of symptoms we have been discussing.

Digestive Disturbances and Debility.

A proportion of cases of debility with symptoms referable to digestive processes could be classified at once as examples of so-called chronic dyspepsia, and severe cases fall into line with the "mucous disease" described by the late Dr. Eustace Smith.[10] But among all these debilitated children constipation or loose stools—much more frequently the

former—loss of appetite, abdominal pain, threadworms, and mucous discharge occur with considerable frequency, and it is only when these symptoms show themselves prominently in the history and clinical picture that the condition is labelled "dyspepsia." The word "dyspepsia" is unsatisfactory, as it implies local disturbance in the alimentary tract, and tends to direct our attention from the wider and more important basis upon which the debilitated state develops. I may instance in this connexion the symptoms of threadworms. Few fidgety children escape being treated for worms, the reason being that parents have learnt to appreciate how frequently threadworms appear in the stools of such children. The parasites may occur temporarily in the excreta of healthy children, yet their continued presence is an indication of an underlying state of the bowel wall which makes it possible for the worm to establish itself. Exactly similar clinical states are seen in children whose stools are free from worms, but which contain large quantities of mucous material.

We are dealing, I believe, with a constitutional and nutritional disturbance in which all the systems of the body are involved, but in which the alimentary tract and digestive function are more particularly implicated. There is an impairment of the defence mechanism, and a defect both in the secretion of the different digestive juices and in the absorbing powers of the bowel wall. If this view is accepted then, notwithstanding the assertion of the bacteriologist and the pathologist that microbic and toxic absorption from the intestinal tract is unlikely, it is not unreasonable to believe that many of these toxaemias arise within the digestive system.

It is this conception of the debilitated state which leads me to suggest that we are dealing with a health defect which belongs to the group of deficiency diseases. Authority is always emphasizing the importance of a better diet for children, yet when the problems of subnutrition are investigated and discussed the importance of the diet is not always insisted upon to the same degree as the other factors of the environment.

This may be illustrated by the results of a recent investigation undertaken on behalf of the Medical Research Council[11] to ascertain the relationship of defective growth and health of children to poverty, diet, and other environmental factors. The main conclusion arrived at is that the chief factor determining growth and health is maternal efficiency, which, we might assume, would be correlated with good and bad feeding; yet the opinion expressed in the report was that the family diet does not explain discrepancies in nutrition and health between different groups of children. Furthermore, the statement is made in the report that a diet containing 10 to 12 per cent. of protein is well balanced with regard to this essential constituent—a statement which seems to me seriously to impair the value of the conclusions finally arrived at.

A 10 to 12 per cent. protein ration is the recognized adult allowance, though even for an adult this may be insufficient if the source of the protein is largely vegetable. It is also likely that the adult members of the family would consume relatively a greater amount of the available protein, especially of the animal type, leaving to the smaller members of the family an amount of protein far below their minimum requirements, together with that part of the household's food which has always been looked upon as safer and more suitable for small children—namely, the carbohydrate. Protein is indispensable and non-interchangeable. The problem of the adult and the child are entirely different, and all authorities agree that the younger the child the greater the amount and proportion of protein needed for maintenance, repair, and growth. Holt and Fales[12] say that the average adult requires approximately 0.45 gram of protein per lb. of weight, and suggest that it is reasonable to suppose that the child requires 0.45 to 0.68 gram per lb. of weight for maintenance alone, and insist that more is necessary for growth, and that for the child animal protein should be given in preference to vegetable. They quote Gillett, who collected information from the literature up to 1917 with reference to the intake of healthy children between 2 and 15 years, as stating the protein intake to be 1.5 to 1 gram per lb. They also quote Gephart and Camerer, who give the amounts as 1.8 to 1 gram per lb. for children and adolescents.

The observations of Holt and Fales upon a series of healthy children over 1 year indicate that approximately 15 per cent. of the total calories taken are protein calories, and that two-thirds of the protein is of animal origin. They also noted that the younger and more active child took the larger proportion. Crozer Griffith[13] states that 20 to 25 per cent. of diet should be protein and 50 per cent. of it should be of animal origin.

Corry Mann[14] has recently compared the effects of adding certain foods to the basic diet of groups of boys living under identical conditions; his results show that the daily addition of a pint of milk causes greater increase in height and weight than the addition of other foods—for example, casein, butter, etc. Although adding casein instead of a pint of milk meant giving some 300 less calories, yet it appears to be inferred that the greater gain in height and weight when milk was given must be due to other constituents than the protein. Leighton and Clark[15] have shown, however, that the gain in weight and height is much the same, whether whole or separated milk is given, and I suggest that this proves that it is the protein which is the important factor.

Hutchison[16] warns us against the danger of protein underfeeding. He writes that habitual underfeeding with protein is more injurious than underfeeding with fat and carbohydrate, and leads to what he aptly calls threadbare tissues. I am satisfied that the majority of these children do not receive anything like the amount of protein necessary for maintenance, repair, and growth. That protein is not the only deficiency is likely. There is a considerable amount of available evidence suggesting that lack of vitamin A is a factor in lowering resistance to infections (Green and Mellanby's[17] work in this connexion is important), and I would mention the work of McCarrison[18] in connexion with lack of vitamin B.

Treatment.

Prophylaxis should be our first consideration, and the future lies in that direction. The problem of the child's diet is bigger than medicine, but not until the medical profession clearly defines what that diet shall be and how it stands in relation to the child's health shall we get authority to realize that diet stands higher than education and psychology in the full development of the child's mental and physical health. It is useless to expect improvement in health by means of throat operations, artificial sunlight, commercial concentrated vitamins, and psychological clinics, while at the same time the child's tissue cell is seriously handicapped by persistent underfeeding of essential food constituents.

Immediate symptoms may be relieved by sugar, alkalis, laxatives, malt preparations, sedatives, and so forth; convalescent treatment and holidays from home are temporarily useful; attention to the throats of properly selected cases may produce immediate improvement; but all these together cannot remove from our midst the debilitated child while the diet remains persistently unsatisfactory.

A CRITICAL STUDY OF UNDULANT FEVER.

FROM A SERIES OF SIX CASES IN THE HOSPITAL FOR TROPICAL DISEASES, LONDON.

BY

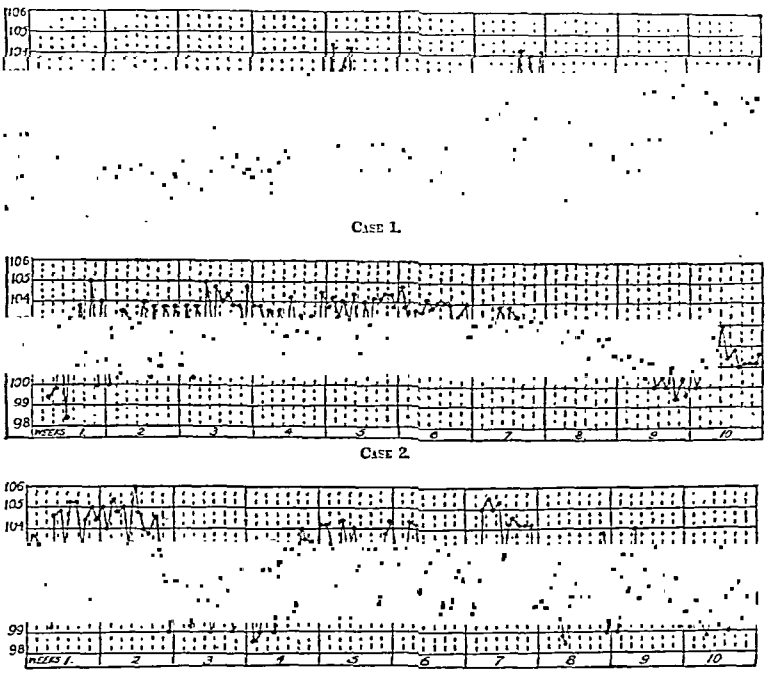
PHILIP MANSON-BAHR, D.S.O., M.D., F.R.C.P.,
PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES, ENDSLEIGH GARDENS, LONDON;

AND

HUGH WILLOUGHBY, M.R.C.S., L.R.C.P., D.T.M. and H.
LATE HOUSE-PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES.

UNDULANT fever (formerly known as Malta fever) is becoming sufficiently rare in practice in England to excite comment whenever it occurs, while the close association, or identity, of *abortus* fever in man and cattle with the classical type of undulant fever is at present attracting universal attention. We therefore consider it an opportune moment to survey a series of cases which have occurred in the practice of this hospital during the last eight years. It shows clearly enough, from the localities from which the patients were derived, the almost universal distribution of undulant fever, for here we have for comparison a series of cases derived from India, East Africa, Peru, and from England itself. No cases, however, have come from the Mediterranean.

There are several points upon which we are at liberty to comment, as can be gathered from the accompanying tables.



CASE 1.

CASE 2.

CASE 5.

Charts in the first ten weeks of the fever in three cases, showing variations in type of temperature.

DIAGNOSIS.

First, as regards the initial diagnosis, it is noteworthy that the impressions recorded were those of typhoid in four cases, malaria in another, and influenza in the sixth. Added to this we might mention that the localization of pain to the margin of the gums and to the eyes in the initial stages of the fever first drew attention to possible defects in these organs. It is fair to state that in making these initial tentative diagnoses there was some justification of a diagnosis of typhoid or malaria in the previous history of the patient. Nevertheless, we can say that all the cases, surveyed as a whole, presented a definite diagnostic syndrome. In this category we include a high initial remittent pyrexia, and it is necessary to emphasize that this may be high (up to 105° F.), resembling in this respect that of true typhoid (see charts). Splenomegaly of a considerable degree was present in every case, and should be considered a prominent factor in making a diagnosis. The intradermal "melitene" reaction of Burnet was tried in three instances and proved to be successful. The skin reaction remained visible for forty-eight hours.

SYMPTOMS.

Arthritic pain was a constant and characteristic feature associated with periarticular effusions which are particularly transient, appearing first in one joint, and then, after a short interval, in a neighbouring one. In addition to the joint pains, the fasciae and bony prominences exposed to the greatest amount of pressure are also affected. We would emphasize that the headache of undulant fever, which is so persistent in the early stages of the infection, has a characteristic of its own. It is not so dull or stuporose as that of typhoid, but it causes intractable insomnia without any appearance of delirium or dulling of the mental faculties. Another characteristic which would assist the practitioner in the differential diagnosis from typhoid is the epistaxis which appears early in the typhoid group, but correspondingly late in the course of undulant fever. It is really part of a general tendency to haemorrhage, as instanced by the bleeding from the gums in three cases, for which the patients had all their teeth removed in the initial stages of the illness. Purpuric eruption resembling that of scurvy appeared in one, and in one particularly protracted case frequent haemorrhages from the urethra were recorded.

Rigors of a subacute character were frequently noted in three cases, with the exacerbation of the fever following upon a comparatively quiescent period. These signs may be taken as affording additional evidence in the differential diagnosis from typhoid, in which they are rare.

The tendency in the later stages of the disease for *Brucella melitensis* to spread by the lymphatic route (a method of spread which is found also in *Br. abortus* in cattle) is one to which hardly sufficient attention has been drawn. There occurs a specific adenitis in this disease (about the fourth month). The glands affected were the cervical group in three, the inguinal set in three, and in two the symptoms were referred to the intra-abdominal glands at the portal fissure, which, if unrecognized, might lead to the suspicion that the patient was suffering from some affection of the gall-bladder. That orchitis may supervene in undulant fever has long been recognized, and it is probably of the same nature as the adenitis already referred to. Testicular pain with some degree of enlargement of the organs themselves was observed in half the number of cases. Profuse and drenching sweats were noted in all. The sweating is universal and occurs mostly at night, necessitating the frequent changing of the bedclothes. A peculiar sour and penetrating odour characterized the sweats in two instances—the "tang" of the odour somewhat resembling that of typhoid to those who are able to appreciate it.

It is hardly necessary for us to comment upon the characters of the temperature charts which are reproduced herewith and which show the curious rhythmical variations. From the figures worked out from our charts the tendency

TABLE I.—*Clinical Symptoms.*

is for the maximum* rise of temperature to take place between 6 and 10 p.m. The lowest temperatures on an average are recorded between 10 a.m. and 2 p.m.

SEQUELS.

Amongst the distressing sequels noted were sciatica of a most persistent character lasting for weeks, and once with pain localized to the sacro-iliac joints, possibly brought about by haemorrhage into the joint cavity. Muscular wasting and laxity of the ligaments of the knee and foot causes a considerable degree of disability during convalescence.

CLINICAL PATHOLOGY.

An analysis of the clinical pathology shows that the blood count throughout all the stages of undulant fever is generally normal. No rise in the number of leucocytes was noted in any instance. On the other hand, one case showed definite changes in the red blood corpuscles, and this was due undoubtedly to persistent purpura (Case 3). *Br. melitensis* was isolated by blood culture in four instances, and it is to be noted that the organism can be isolated from the blood stream at any period of the disease up to absolute convalescence, even when the patient's condition would lead one to suspect a septicaemia, and it is probably true that the organism is not actually destroyed in the blood stream, but that the infection "burns itself out." It is to be noted, too, that in order to secure success in blood culture the inoculated medium must be incubated for at least ten days; the same applies to the cultivation from the urine. In one instance success was obtained from a mid-stream specimen which proved to be uncontaminated; on the other hand, no success was obtained with catheter specimens.

TABLE II.—*Pathological.*

	Case 1.	Case 2.	Case 3.	Case 4.	Case 5.	Case 6.
R.B.C.	4,900,000	4,770,000	3,420,000	5,000,000	—	4,000,000

Agglutinates:						
Br. melitensis	1 in 640	1 in 80	1 in 1,280	1 in 640	1 in 620	1 in 500
B. typhosus	—	—	—	1 in 320	—	—
Br. abortus	—	—	—	1 in 480	—	—

* *Maximum rises:* 2 a.m., 7 per cent.; 6 a.m., 14 per cent.; 10 a.m., 2 per cent.; 2 p.m., 6 per cent.; 6 p.m., 33 per cent.; 10 p.m., 38 per cent.

SEROLOGICAL TESTS.

The agglutination test with dead emulsions of *Br. melitensis* (Mediterranean strain) proved of diagnostic value in every case when performed by the macroscopic method. On each occasion the initial diagnosis was made by this test on Garrow's agglutinometer, which proved to be as reliable and much more expeditious, than the tube method. We would emphasize that the titre of agglutination appears to have no bearing on the prognosis, nor does it indicate in any way the probability of isolation of the organism by blood culture. For instance, in the most severe case of our series (Case 2) the titre of agglutination to *Br. melitensis* never rose above 1 in 80.

TREATMENT.

On the question of treatment it is a matter of regret that we have nothing very positive to record. As regards the efficacy of vaccine we prefer to keep an open mind. As will be seen by Table III, all varieties of vaccines were tried. The effect of stock vaccines made from standardized laboratory cultures of *Br. melitensis* in doses of from 60 to 300 million were compared with those of autogenous vaccines made from organisms isolated from blood culture and with a polyvalent vaccine issued by the Medical Research Council and composed of many strains. We could obtain no evidence that the use of vaccines given over a prolonged period of three months or more in any way modified the course of the disease.

Argochrome, a silver methylene blue compound prepared by Merck's and recommended by Nocht, was tried in one case by rectal enema. Although the methylene blue was absorbed and appeared in the urine, it seemed to have no

beneficial effect at all. Intravenous injections of eusol in doses of 50 c.cm. (double strength in distilled water) was tried in one case, and appeared to have some influence in modifying the fever.

In conclusion we would like to [illegible] edness to Dr. J. T. Duncan of the London [illegible] t Tropical Medicine, and Messrs. F. W. Foste[illegible] for their kind assistance with the laboratory work undertaken in connexion with the above series of cases.

AN IMPROVED DIFFRACTION METHOD FOR DIAGNOSING AND FOLLOWING THE COURSE OF PERNICIOUS AND OTHER ANAEMIAS.*

BY

ADRIANUS PIJPER, M.D.,

PATHOLOGIST TO THE PRETORIA HOSPITAL, PRETORIA, SOUTH AFRICA.

Principle of Method.

WHEN a beam of white light is sent through a blood smear it is broken up (diffracted) by the blood cells into the spectral colours. From the distribution of the colours the *mean diameter*, the *degree and quality of anisocytosis*, and the *degree of poikilocytosis* of the red cells can be determined. The application of the method is simpler than the description. No mathematics are required to read Figs. 3 to 11, where the half-circles illustrate the diffraction spectra exactly as they appear on the screen of the apparatus, two at a time, thus facilitating comparison and reading of results. "Diffraction method" and "diffraction micrometer" are suggested as suitable names.†

Need for Method.

The increasing incidence in many countries of Addison's (pernicious) anaemia,[4] together with Minot and Murphy's discovery of the liver treatment,[5] has led to the publication of numerous papers. A curious feature of this literature is the scantiness or absence of numerical data on the diameter of the red blood cells, although the correctness of Hurst's statement,[6] "the most characteristic features of the blood in Addison's anaemia are the anisocytosis and the increase in the average size of the red cells," is at the same time very generally admitted. Red cell measurements evidently are still universally regarded as "research," and not as "routine." This is due to the lack of a suitable method. Direct microscopic measurement,[7] and photographic methods,[8] are manifestly too laborious.

Advantages of Method.

In its present form the advantages of the method are:

1. The only material required is a properly made, unfixed, unstained blood smear. Such smears remain serviceable for years, thus allowing dispatch over long distances, and storage for future reference. Fixed and stained smears are less suitable.

2. The method expresses in tenths of microns the mean diameter of at least one million red cells.

3. The method expresses in tenths of microns the diameter of both the largest and the smallest cells which are present in the smear in considerable number. In other words, it gives the degree and quality of the anisocytosis present. The information thus gained is not sufficient to construct a frequency curve, but ample for practical purposes, as it indicates the essential features of the curve.

4. The method gives the degree of poikilocytosis present in the blood smear.

5. All these determinations together do not take more time than a haemoglobin estimation.

6. The cost of the apparatus is moderate.

7. The method allows the direct comparison of the essential characteristics, mentioned above, of any two blood smears. This is helpful in following the course of a disease. (See Figs. 9 to 11.)

As I am dealing with practical issues only, I shall not go into the controversy about the effect of drying upon the diameter of the cells, nor discuss the problem whether there is such a thing as "the exact diameter" of a red cell.

Theory of Method.

The thin end of a properly made blood smear can be regarded as a diffraction-grating, the cells being opaque and the plasma transparent. A beam of white light passing at right angles through such a smear is diffracted at the edges of the cells, and the resulting light waves, collected by a lens placed behind the blood smear, will produce a series of concentric circular spectra in the focal plane of the lens. The size of these spectra is a function of the diameter of the red cells of the smear, the white cells being too few to count.

For practical purposes only the innermost of the circular spectra need be considered, as being the brightest. The formula expressing the relationship between the various factors, the derivation of which can be found in textbooks on physics, is:

$$d = \frac{1.7\lambda\sqrt{f^2 + r^2}}{r}$$

in which (d) is the diameter of the red cells, (f) the focal distance of the lens used, (r) the radius of the coloured circle in the (innermost) spectrum, and (λ) the corresponding wave-length. The formula shows that the diameter of the cells can be calculated from the radius of any coloured circle, that the diameter of the coloured circles and the diameter of the cells vary inversely, and that a lens with a longer focal distance will produce larger spectra.

So far the matter has been treated as if the elements of the diffraction-grating (the red cells) were all of equal diameter. The diameters of the red cells of a healthy person, of course, follow the curve of normal variation. Therefore, assuming that the mean diameter in such a case is 7.3μ, there will be more cells of this diameter than of any other, but there will also be an ever-decreasing number of cells deviating more and more, in opposite directions, from this mean value. The spectrum produced by the cells measuring 7.3μ will naturally be the brightest, these cells being the most numerous. On this spectrum will be superimposed the weaker spectra belonging to the other, smaller and larger, cells. In Fig. 1 are drawn to scale, as calculated from the formula, the spectra thrown by cells measuring 7.3, 6.7, and 7.9μ. Intermediate cells will, of course, throw intermediate spectra. The drawing shows that all these superimposed spectra will practically not affect the position of the bright yellow circle produced by cells measuring 7.3μ. They will make the whole yellow circle broader, and the superimposed red and green will dilute the colour. This means that the brightest yellow circle will remain the expression of the mean diameter of the red cells, and that from that yellow circle the mean diameter can be calculated (wave-length 0.59μ).

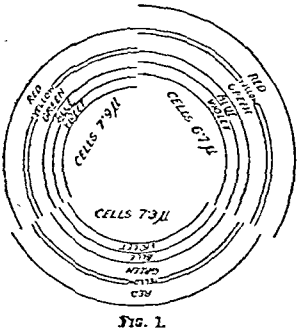

FIG. 1.

From Fig. 1 it is also obvious that the innermost violet circle always is the expression of the largest cells present in a blood smear in sufficient number to produce visible colours, and that similarly the outermost red circle represents the smallest cells which are present in the blood

* Part of the apparatus used in working out the diffraction method was bought by aid of a grant from the Union Government Research Grant Board.

† It has repeatedly been brought to my notice that Thomas Young (1773–1829) employed the identical *principle*, first for the measurement of wool fibres (wool=cotton), and later of red blood cells. I cannot regard this as a reason to call my *apparatus* an etiometer, as Emmons[1] has suggested. When, in 1918, I discovered that bacterial colonies can produce diffraction spectra, I started using this phenomenon for measuring bacteria.[2] From this beginning I developed my diffraction method of measuring red cells[3] in complete ignorance of Thomas Young's work.

smear in similar number. By determining the points where the violet and red colours vanish, and substituting these radii and the corresponding wave-lengths (for red 0.70μ, and for violet 0.40μ) in the formula, both the diameter of the "smallest" and the "largest" cells present in the blood smear *in considerable number* can be calculated.

The method misses the very largest and the very smallest cells, because they are too few to produce a visible effect. For the same reason direct microscopic measurement does not achieve much more in this respect.

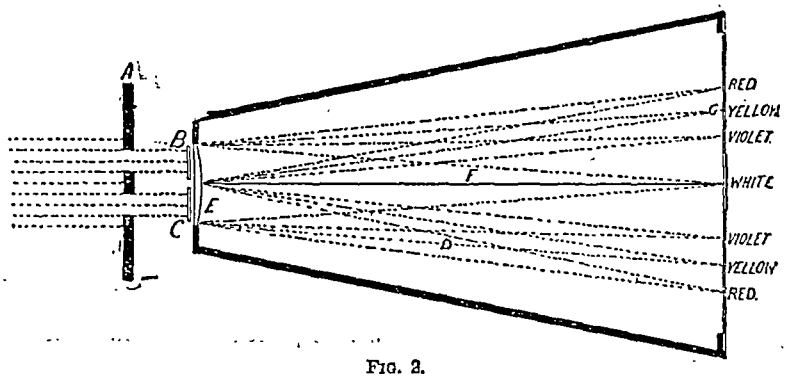

FIG. 2.

The advantages of direct microscopic measurement lie in the construction of a frequency curve. The important features of such a curve are the position of the top and the shape of the curve (narrow or wide, symmetrical or not). From the above it is evident that, generally speaking, the width of the spectrum corresponds to the width of the curve, that the position of the top of the curve is given by the position of the yellow circle, and that the relative positions of the extreme red and innermost violet circle with regard to the yellow circle serve to show whether the curve is symmetrical or not. Healthy people by this method usually show a symmetrical anisocytosis—such as mean diameter 7.3μ, "largest" cells 7.9μ, "smallest" cells 6.7μ.

For estimating the degree of poikilocytosis it must be remembered that the rounder the cells are the better the grating will be. Poikilocytosis thus affects the brilliancy of

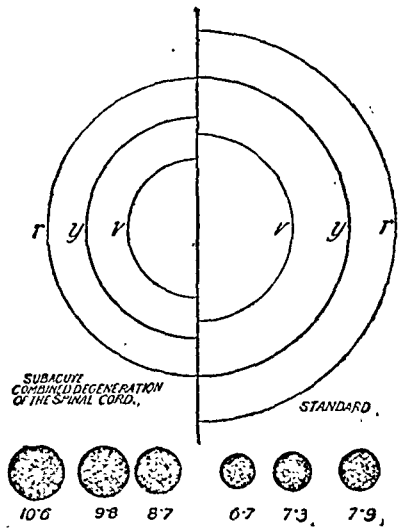

FIG. 3.

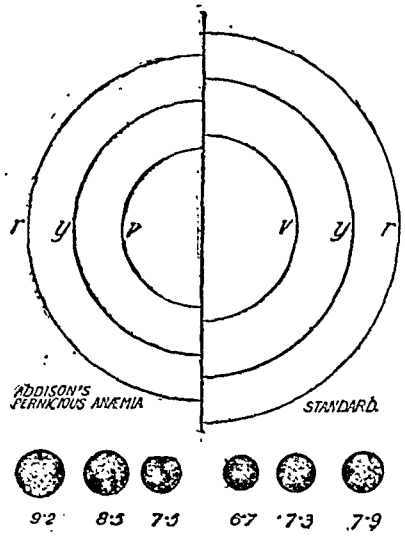

FIG. 4.

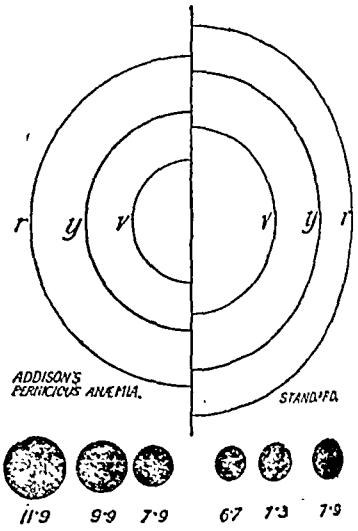

FIG. 5.

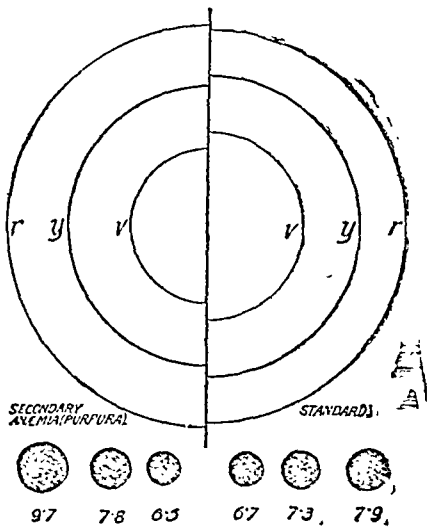

FIG. 6.

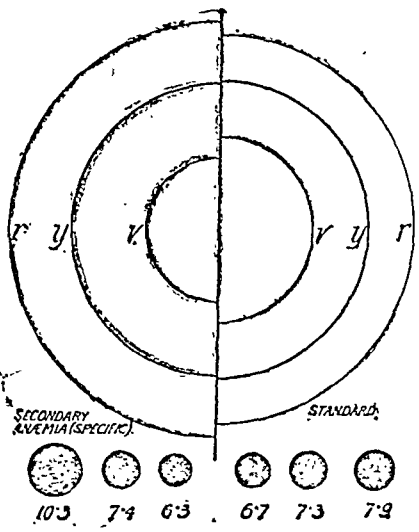

FIG. 7.

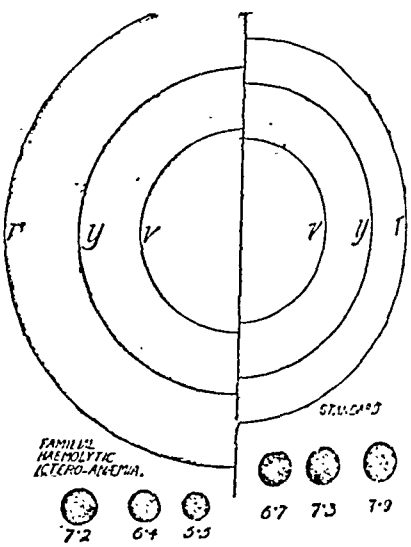

FIG. 8.

FIG. 3.—Typical small spectrum of subacute combined degeneration of spinal cord. Spectrum not proportionally narrower, indicating more anisocytosis than normal, and towards small side (10.6, 9·8, and 8.7μ). No poikilocytosis. Haemoglobin 70 per cent., red cells 3.5 million.

FIG. 4.—Typical small spectrum of an early case of Addison's pernicious anaemia. Little anisocytosis, asymmetrical, towards small side. Some poikilocytosis. Haemoglobin 34 per cent., red cells 2.7 million.

FIG. 5.—Late case of Addison's pernicious anaemia. Small spectrum, very marked anisocytosis, symmetrical. Marked poikilocytosis. Haemoglobin 20 per cent., red cells 3.6 million.

FIGS. 6 AND 7.—Typical broad spectra of secondary anaemia. The heavier the anaemia, the broader the spectrum. Late syphilis often gives a spectrum like Fig. 7. Anisocytosis very marked, asymmetrical, towards large side. Often in such cases poikilocytosis not marked, and mean diameter not much changed.

FIG. 8.—Strikingly large spectrum, diameters of cells very small, as typical for familial haemolytic ictero-anaemia, although cell volume may be large.[9] Little anisocytosis, symmetrical. Poikilocytosis present. Hereditary element traced in abnormally small cells in relatives on father's side, in father, and in brothers and sisters; mother's cells normal. Similar investigation seems indicated in relatives of patients of Addison's pernicious anaemia, to throw light on question of heredity.[10]

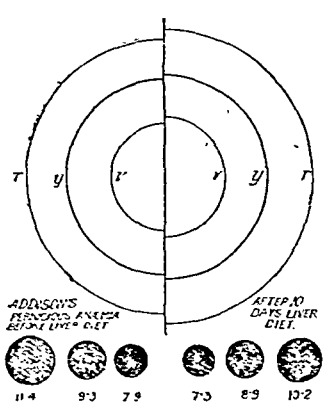

FIG. 9.

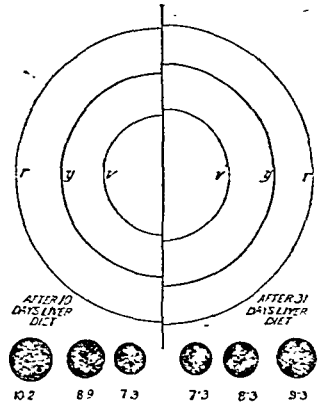

FIG. 10.

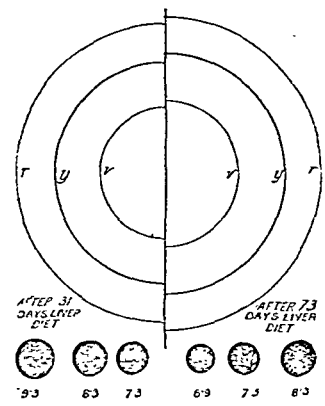

FIG. 11.

FIGS. 9 TO 11.—These three figures illustrate the improvement brought about through liver diet in a patient with Addison's pernicious anaemia. Spectra not compared with standard, but with other smears from the same patient. The haemoglobin rose from 32 to 89 per cent., and the red cells from 1.4 to 5.2 million during the same period.

the colours, and also the number of concentric spectra which become visible round the bright first one. From this the poikilocytosis can readily be estimated, especially as the method permits a direct comparison with a "standard" (Figs. 3 to 11). I need not detail why the method is not absolutely correct. Fair comparison with other methods shows that its advantages outweigh its inexactitudes.

Technique of Method.

A beam, about 6 cm. broad, of parallel light rays, from the sun, or from an artificial source (arc or pointolite) with condenser, is directed towards the apparatus (Fig. 2). Through two square holes, of 1.5 cm., in the screen "A" it reaches the thin ends of blood smears on the microscope slides "B" and "C," which are fixed to the front of the box "D" by clamps. The box is of wood or metal, 25 cm. high and 40 cm. long; the back is a ground glass plate "G," of 25 by 25 cm., with its ground surface towards the light. In front, in the centre, is the lens "E," a simple lens, of 6 cm. diameter and 40 cm. focal length, plano-convex, such as may be bought from an optician for a few shillings. The partition "F" is exactly in the middle, in close apposition to the lens and the ground glass.

It is preferable to have the apparatus in a dark room, and admit the beam through a hole in the wall; if this is not possible other means must be found to exclude all foreign light from the ground glass. It is a help if a disc of black cardboard is pasted over the centre of the ground glass, as the white light which is concentrated there is dazzling, and the centre of the disc can at the same time serve as a starting point for the measurement of radii.

As the partition "F" cuts off one-half of either set of spectra, the ground glass will show two sets of coloured half-circles in spectral colours, separated by a thin black line, the shadow of the partition. Their actual appearance is illustrated by Figs. 3 to 11. The three half-circles in each case represent the position of the extreme red, the bright yellow, and the innermost violet circle of the innermost spectrum, as indicated by the letters "*r*," "*y*," and "*v*."

A "standard" blood smear is obtained by collecting blood smears from "healthy" persons, comparing their diffraction spectra by using them in the apparatus two by two, and picking out one which gives medium values for the radius of the yellow circle, and minimum value for anisocytosis (=broadness of spectrum). It will be found that minor differences in these respects occur between individuals. These differences remain constant for long periods, and perhaps for ever, but intercurrent diseases may at least temporarily affect them. The meaning of these differences, their bearing on blood groups, their pathological significance, and other points in this connexion (day and night changes, effects of exertion), I shall treat in a later paper.

For the chosen standard smear the radii of the yellow, innermost violet, and extreme red circles are then carefully once and for all determined with a pair of compasses. With my lens, which has a focal distance of 40.4 cm., they measure respectively 56, 35, and 73 mm. From these values the formula gives for the mean diameter 7.3μ, for the largest cells 7.9μ, and for the smallest cells 6.7μ.

In determining the radius of the extreme red circle, it must be borne in mind that, as the second spectrum overlaps the first (or innermost) spectrum to a certain extent, the extreme red circle borders on the green circle of the second spectrum. Together these two colours produce a greyish zone, and the extreme red must be localized there where this grey zone ends, and the green appears quite pure. In localizing the innermost violet one must choose the spot where purple fades into yellow.

The standard radii being known, the radii belonging to any blood smear can easily be estimated by direct comparison, as shown by Figs. 3 to 8. Where the differences are small, the direct comparison makes them appear quite obvious, and for large differences an error of a millimetre in estimating the difference is not important. For accurate work compasses are useful. The values obtained for the radii can be converted into cell-diameters by calculation with the formula, but, of course, it saves time if from the formula a table or a curve is prepared from which the cell-diameters belonging to any radius can just be read off.

It is not always necessary to perform measurements and calculations, as often a glance at the spectra gives sufficient information (see Figs. 3 to 8) to make or exclude a particular diagnosis.

Application of Method.

The method has now been used by me on hundreds of smears, and its diagnostic results have been checked by other methods and observations. It has cleared up many difficult cases. In suspected cases of pernicious anaemia where it gave a typical secondary anaemia spectrum further examination of the patient has revealed early malignancy or duodenal ulcer. It has become an essential routine method, and as such has occasionally given a dramatic diagnosis in unsuspected cases of Addison's pernicious anaemia, aplastic anaemia, subacute combined degeneration of the spinal cord, and familial haemolytic ictero-anaemia, which otherwise might easily have escaped notice.

Note.—Figs. 3 to 8 show the differences between the standard and certain typical pathological spectra observed by me. At the bottom of Figs. 3 to 11 the small filled-in black circles represent, drawn to scale, the cells of mean diameter, the "largest"

and the "smallest" cells, as calculated from the radii of the half-circles shown. The diameters of these cells are given in microns.

LIVER TREATMENT OF PERNICIOUS ANAEMIA:

ITS EFFECT ON THE POLYNUCLEAR LEUCOCYTE COUNT OF COOKE.

BY

G. W. T. H. FLEMING, M.R.C.S., L.R.C.P., D.P.M.ENG.,

DEPUTY MEDICAL SUPERINTENDENT AND PATHOLOGIST, DORSET COUNTY MENTAL HOSPITAL.

IN the course of routine blood examinations of the patients of this hospital, consisting of the polynuclear count of Cooke and the Schilling haemogram, it occurred to me to investigate the influence of liver treatment on the polynuclear count in a case of pernicious anaemia which was to undergo that treatment.

The polynuclear count of Cooke is simply a modification of the original Arneth count. The original Arneth count was far too complicated, and as a direct result of this we have two modifications in clinical use at the present day: the polynuclear count described by Cooke and Ponder[1] in 1927, which most closely resembles the Arneth count, and the Schilling haemogram,[2] which divides the neutrophil leucocytes into those with one lobe to the nucleus, including in this the myelocyte and the metamyelocyte, and those cells with more than one division to the nucleus. In this study we are only concerned with the polynuclear count. This gives a much more delicate picture of the leucocytes than either the Schilling haemogram or a total white count *plus* an ordinary differential one.[3] The Schilling haemogram does not indicate any abnormality in pernicious anaemia apart from an inconstant lymphocytosis.

In the polynuclear count as described by Cooke and Ponder[1] the percentage of leucocytes with one lobe to the nucleus is multipled by one, the percentage with two lobes by two, and so on up to the percentage with five or more, which is multiplied by five. The numbers obtained added together and divided by 100 give the weighted mean number of lobes of the nucleus per leucocyte. The average number in each group in health is about—

I.	II.	III.	IV.	V.
10	25	47	16	2

This gives a normal weighted mean of 2.75. The average varies slightly from individual to individual and with individual workers. Arneth's mean is normally given as 2.76, and Cooke in 1925[4] gave his normal as 2.70. My own mean, taken from members of the staff who are healthy, is 2.65. The normal mean can fairly definitely be taken as lying between 2.50 and 2.80. The first two groups of the count (I and II) are spoken of as the left-handed columns, and groups III, IV, and V as the right-handed columns. The numbers in the two groups I and II added together constitute the left hand, and III, IV, and V the right hand. I have divided the right hand by the left hand and called this the index of right-handedness (R.H.) in tables. Bushnell and Treuholtz[5] suggested adding together groups I and II and half of group III. This is referred to in the tables as B.T.

Naegeli[6] described a pronounced hypersegmentation of the neutrophil nucleus in pernicious anaemia. Arneth[7] in 1920 described the "Rechtsverschiebung" or shift to the right which accompanies the neutropenia characteristic of pernicious anaemia. Cooke[4] in 1925 showed that in uncomplicated pernicious anaemia there was an increase in the number of cells in groups IV and V and a decrease in groups I and II. In group V are those cells with five or more lobes to the nucleus; in pernicious anaemia we often find cells with seven or eight lobes, and in the case of the macropolycyte[8] there may be ten to fourteen lobes. This means, of course, that the weighted mean and the index of right-handedness are both high. Jedlička and Béranek[9] report the neutrophil picture in 36 cases of pernicious anaemia. There is nearly always leucopenia, although there are cases with neutrophil leucocytosis of long duration. These authors found an increase of the number of cells with more than three lobes to the nucleus, but also a shift to the left—that is, a dissociation of the blood picture. They consider this dissociation of the blood picture to the right as well as to the left a characteristic of pernicious anaemia. However, Arneth[10] has subsequently demonstrated that this dissociation to the right and to the left also occurs in lymphatic leukaemia. Jedlička and Béranek point out that this dissociation is most marked at the height of the disease and may disappear during remission. Arneth had previously suggested that the myelocytes observed by some authors are really erythroblasts, so accounting for a certain number of cells in group I. Krjukoff[11] describes a similar dissociation in sprue—the appearance of myelocytes together with an increase in the number of hypersegmented forms. This will be referred to later. Whitby[12] describes how in two out of four cases treated with liver the relative lymphocytosis disappeared and the differential count became normal apart from the eosinophilia. He did not describe any changes in the neutrophils. Other writers in the *Lancet* inquiry into the effects of liver treatment[13] show usually a return to the normal number of leucocytes, but give no detail of the neutrophil picture.

Cooke gives the following numbers of cells per group in his cases of pernicious anaemia. The respective indices are given in the last three columns.

Case.	Group.					Weighted Mean.	B.T.	R.H.
	I.	II.	III.	IV.	V.			
1	11	24	49	15	1	2.71	53.5	1.5
2	6	20	39	22	11	3.08	45.5	2.5
3	6	27	40	22	5	2.93	47.0	2.3
4	7	20	44	24	5	3.00	47.0	2.7
5	7	16	29	39	9	3.27	37.5	3.5
6	12	31	26	20	8	2.78	59.0	1.1
7	20	31	17	16	16	2.77	53.5	0.9
8	16	22	32	16	14	2.90	54.0	1.4
9	10	15	38	24	13	3.05	45.0	3.0
10	6	20	42	20	12	3.12	47.0	2.1

Of these, Cases 7 and 8 both show a dissociation of the count and Case 6 to a lesser degree. Our case before liver treatment showed—

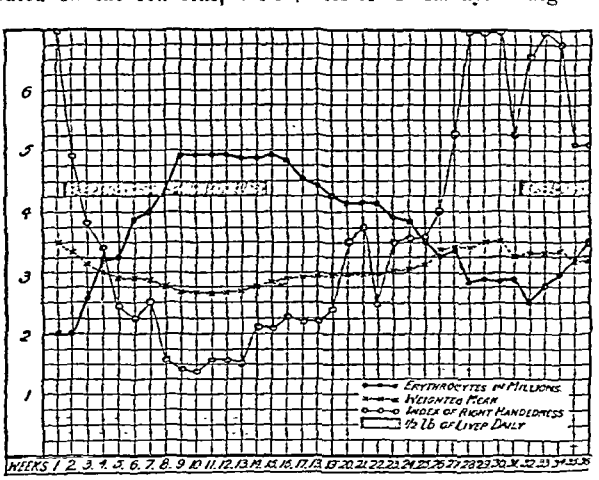
Group I	1
" II	16
" III	33
" IV	32
" V	11
Weighted mean	3.33
B.T.	36.5
R.H.	4.53

Possibly Cases 1, 6, and 7 of Cooke's series had some intercurrent infection or hidden septic focus causing the low weighted mean.

It occurred to me that possibly liver treatment might bring the large number of cells in groups IV and V down to a normal level as the blood returned to normal, and this is precisely what happened. As the red count rose so the weighted mean and right-handed index fell until they reached what was apparently the normal level for the particular individual, and there they remained constant so long as the liver treatment was continued and for some little time afterwards. The two indices then began to rise again as the number of erythrocytes fell, but not quite so rapidly as had happened at the beginning of the liver treatment. When the second course of liver treatment was begun the two indices fell as the erythrocyte count rose. The accompanying chart gives a clear picture of the result. The index of right-handedness shows much more than the weighted mean the change in the polynuclear count, but is obviously too sensitive to change when the numbers in groups I and II are small.

COMMENT.

In the usual clinical descriptions of pernicious anaemia so much interest is concentrated on the red cells, their haemolysis, size, shape, etc., that the leucocytes have come in for very little attention. It seems, however, that the leucocyte changes may in the end produce more convincing indication towards the elucidation of the etiology of the syndrome than has in the past been thought of. A shift to the right of the Arneth or polynuclear count is not common. It is never found in conditions in which there is any infective process at work. The onset of an infective process swings the count across to the left at once, where it stays until the infection subsides. According to Cooke[1] the shift to the left is not so pronounced as it would be in the case uncomplicated by pernicious anaemia. The conditions in which a shift to the right have been described are pernicious anaemia, sprue, and, according to Arneth,[10] lymphatic leukaemia. Dr. Newham of the London School of Tropical Medicine was kind enough to send me some blood films from two well-established cases of sprue. Both these showed a well-marked shift to the right, with the typical blood picture one has learned to associate with pernicious anaemia. Whether *Bothriocephalus latus* anaemia shows a shift to the left or not I am unable to say.



A recent article by Carbonara[11] is extremely interesting, for he found a shift to the right of the Arneth count associated with liver disease. In view of the effect of liver treatment in pernicious anaemia, this work of Carbonara's requires careful investigation and confirmation. If confirmed it certainly would appear to be a link in the chain of evidence. Sprue is looked on by Ashford[15] as a glandular insufficiency on which is superimposed a gastro-intestinal infection with *Monilia psilosis*. However, the more recent work of Lye, Zerfas, and Cornwell[16] has shown that the number of isolations of monilia from stools and gastric contents is no greater in pernicious anaemia than it is in other cases of severe anaemia and gastric achylia. These authors conclude that monilia is unimportant as an etiological factor in either pernicious anaemia or sprue. Elders[17] states that sprue is a deficiency disease, and, after comparing sprue and pernicious anaemia, concludes with the statement that "pernicious anaemia is, like sprue, a deficiency disease, and as such should be curable, or at least amenable to improvement, by well-chosen food." This statement was made at the end of 1924, and how true his words were is seen from the subsequent work of Whipple and the introduction of the Minot-Murphy diet. On the other hand, Newham, Morris, and Manson-Bahr[18] conclude that pernicious anaemia and sprue are two distinct clinical entities, although having several features in common.

Knott[19] found that after liver treatment in pernicious anaemia there was no diminution in the intensity or the nature of the intestinal infection, that the disappearance of the indirect van den Bergh reaction did not necessarily correspond with a reduction in the intestinal infection, and that cases in which a return to a normal blood picture had occurred might still show just as high a bacterial content of the faeces as when in the acutely anaemic stage. In the face of this conflicting evidence, which tends against the infectious etiology of pernicious anaemia, we are driven back on to the theory propounded by Piney[20] that pernicious anaemia can only occur in persons who have a remnant of megaloblastic tissue in the liver—that is, that it is essentially a constitutional disease. This is supported by the frequent familial incidence, and also by the fact that achlorhydria, which is invariably present in pernicious anaemia, also commonly occurs in several members of one family. Naegeli[21] thinks that there is possibly some constitutional weakness or abnormality of the bone marrow, due perhaps to the retention of megaloblasts since childhood. He quotes Schaumann as having observed cases of *Bothriocephalus latus* anaemia which recovered, but some of which later suffered from real cryptogenetic pernicious anaemia. This supports the constitutional origin of the syndrome. Haden[22] looks on pernicious anaemia as due primarily to an inability of the bone marrow to mature red cells, resulting from the lack of some specific substance, and thus would classify it as a deficiency disease, the deficiency not necessarily being hepatic. He concludes by saying: "It is more likely due to a failure of absorption, or an elaboration in the intestinal tract of the specific maturating substance, perhaps resulting from a long-existent achlorhydria."

CONCLUSIONS.

1. A case of pernicious anaemia treated with liver showed an abolition of the marked shift to the right of the polynuclear count as the total blood picture returned to normal. When liver treatment ceased the polynuclear count moved over to the right again, to be brought back by more liver treatment.

2. A plea is made for a closer study of the leucocytes by those clinicians who have large numbers of cases of pernicious anaemia to deal with, in the hope that this study may lead to a better understanding of the syndrome than the study of the erythrocytes has done.

3. At the same time it would be of greater scientific interest if *all* reports of cases of pernicious anaemia contained an account of, in addition to what is called the "typical blood picture" and the achlorhydria, (*a*) the leucocyte picture, including the polynuclear count or the Arneth count, in addition to Schilling's haemogram; (*b*) the icterus index; (*c*) the indirect van den Bergh reaction; (*d*) the Price-Jones curve. The diagnosis of pernicious anaemia is made much more accurate in the presence of (*a*) to (*d*).

My thanks are due to Dr. P. W. Bedford for permission to make use of the clinical material and to Dr. Newham for the blood films from cases of sprue.

JEJUNAL ULCER ASSOCIATED WITH TESTICULAR PAIN.

BY

A. C. HAMPSON, *M.C.*, M.A.CAMB., M.R.C.P.LOND.,

PHYSICIAN WITH CHARGE OF OUT-PATIENTS, DREADNOUGHT HOSPITAL, GREENWICH; ASSISTANT PHYSICIAN TO QUEEN MARY'S HOSPITAL, STRATFORD.

THE following case appears to be worth recording on account of the unusual symptoms.

A man, aged 37, had mumps as a child, but otherwise no illness worthy of note till December, 1915, when he was invalided from the army with dysentery. Shortly after returning to duty he was buried by a shell. He was apparently concussed, and immediately afterwards the thyroid gland was seen to be much enlarged; it gradually became smaller, and now seems to be normal. Shortly after the concussion he began to have attacks of epigastric pain, associated with hunger, about half an hour after meals, and tenderness in the epigastrium to the right of the mid-line. At this time he was having irregular meals and smoked heavily; the pain was relieved by food for about half an hour, and then returned increased, being frequently associated with vomiting. At the beginning the attacks lasted about a week, pain appearing after every meal during this time; there were intervals of two or three months during which he was entirely free from symptoms. The attacks were specially severe during the winter, and were usually accompanied by enlargement of the thyroid gland. They gradually became more frequent and of longer duration.

In July, 1919, he had an attack of unusual severity, and three weeks later, while working in his office, he experienced sudden acute abdominal pain associated with repeated vomiting. An operation was performed for perforated duodenal ulcer, but he was apparently given no instructions as to diet, and he ate what he pleased. He remained well for about two years, after which the symptoms appeared again more acutely, and the pain and tenderness extended across the epigastrium. The stools now showed the presence of occult blood. He was treated for six weeks by dieting, but was not confined to bed. After a short interval the symptoms returned, and in February, 1925, gastro-jejunostomy was performed; following this, he was put on a moderately restricted diet for two months.

Six months later he again had symptoms, but they were not so acute as before the operation; they came on particularly when the weather was cold. The pain became gradually longer in duration, increasing in intensity during the day, independent of meals, and was not now relieved by food. On the other hand, for the first time he started to be wakened by pain between 2 and 3 a.m. This only occurred if he had taken a meal after 7 p.m.

In August, 1926, he first felt a dull aching pain in the testes at the end of the day, when the epigastric pain was most acute. A suspensory bandage gave little, if any, relief. Gradually the pain in the testes became greater, and appeared earlier in the day, together with pain in the loins. He never had these symptoms except when the epigastric pain was present, and there was no abnormality in micturition.

In May, 1928, he was awakened about 3 a.m. by attacks of pain in the testes, so severe as to necessitate injections of morphine. There was general tenderness in the upper abdomen, especially at a point immediately above and to the left of the umbilicus, where a small lump could be felt. It seemed to be fixed to the deeper tissues, and moved with the pulsations of the aorta. Pressure on the lump reproduced the pain in the back and in the testes. The testes themselves were tender, and there was slight hyperalgesia in the loins. The urine was normal, and examination of the uro-genital tract revealed no abnormality. An *x-ray examination* with a barium meal showed a jejunal ulcer in the situation of the tumour. Occult blood was present in the stools. The patient was confined to bed, and treated medically on a strict diet. The pain was rapidly relieved and the tumour gradually disappeared. Since then he has remained on a modified diet, and has become a non-smoker. He has remained free from symptoms, has put on 2 st. in weight, and remarks that he has never felt better in his life.

The two main points of interest in this case are: the association of thyroid enlargement with attacks of epigastric discomfort due to duodenal ulcer, and the pain in the testes and the loins. With regard to this pain, four points may be emphasized. (1) Testicular pain was never present except when there was pain in the epigastrium. (2) Pressure on the tumour produced pain in the testes. (3) Subsidence of the pain, both in the testes and in the epigastrium, coincided with the disappearance of the tumour. (4) The tumour moved with the pulsations of the aorta, to which it appeared to be fixed. The first three of these points suggest that both testicular and epigastric pain had a common origin.

X-ray examination showed that the jejunal ulcer and the tumour were situated just to the left of the mid-line, at the level of the intervertebral disc between the third and fourth lumbar vertebrae. The sympathetic nerve supply, both of the kidneys and the testes, is derived from the twelfth thoracic and first lumbar segments of the cord. These nerves form a plexus in front of the aorta, and branches from this plexus accompany the renal arteries to the kidneys. Branches from the same plexus accompany the spermatic vessels to the testes, and are also distributed to the ureters. Thus the inflammatory mass associated with the ulcer was situated where the sympathetic plexus, in front of the aorta, would be involved and the patient's symptoms suggest that pain can be referred to a viscus through sympathetic nerves. The phenomenon also suggests an explanation for the testicular pain in ureteric colic, other than the one advanced by Mackenzie, that both these structures are supplied by branches of the genito-crural nerve.

Periodic stimulation of the sympathetic plexus by the inflammatory mass might be due to periodic vascular engorgement or to actual traction on the plexus. The latter seems the more likely explanation. The traction could be produced by gastric movement, the site of the ulcer being fixed. If this explanation is correct, the coincidence of the epigastric pain with that in the testes suggests that pain due to an ulcer is associated with movement of the diseased viscus, whether the movement be tonic or peristaltic in origin. The persistent character of the pain suggests an alteration in tone as the more likely explanation.

TRAUMATIC FAT NECROSIS OF THE BREAST

BY

P. J. MOIR, *M.C.*, M.B., F.R.C.S.,

ASSISTANT SURGEON, GENERAL INFIRMARY, LEEDS; SURGEON, LEEDS PUBLIC DISPENSARY.

THE condition of traumatic fat necrosis of the breast was first described in America in 1920 by Lee and *Adair*,[1] who published two cases. They wrote further on the subject in 1922[2] and in 1924,[3] and since then several cases have been described. The first published in this country was by Keynes.[4] Later, Hadfield[5] wrote on the subject.

In these cases, following trauma, there developed in the breast a lump which clinically appeared to be a carcinoma but on microscopic examination areas of fat necrosis only were found, and no evidence of malignant disease was present. Farr[6] was able to produce experimentally the characteristic lesions by pinching with forceps the subcutaneous fat of young pigs. Sections of the injured area showed the typical histological picture of fat necrosis. Farr concluded that in an area of traumatized fat the lipolytic enzyme present in fat and blood is liberated, and acts on the neutral fat, breaking it down into its components—fatty acid and glycerol. These substances form the irritant which gives rise to the foreign body reaction producing the lesions of traumatic fat necrosis. Although trauma seems to be the usual factor in the published cases, Gottesman and Zemansky[7] came across a case in which this cause could be eliminated. Further they analysed 78 cases of non-malignant breasts, and in 14 found some stage or degree of fat necrosis. They concluded that factors other than trauma may explain the phenomenon, and that the escape of fatty material from a dilated duct and its subsequent decomposition plays a part in the cause of this condition.

Professor M. J. Stewart calls the condition subacute panniculitis. He tells me that in his experience it is not uncommon, and he has met with it in the *anterior*

in fat removed from the femoral canal, and in the subcutaneous fat in different situations in the body as well as in the breast. In a paper on xanthema and xanthosis[8] he writes:

"When adipose tissue is involved in a subacute inflammatory process it is not uncommon for aggregations of large, foamy endothelial cells to make their appearance in the interstices of the tissue between the oil droplets. Like foamy cells elsewhere, they are filled with cholesterin fat, and often they may be seen going on to the formation of foamy giant cells. Rarely pure cholesterin crystallizes out, and a remarkable histological picture results, in which foamy cells, giant cells, cholesterin clefts, and foci of necrosis are mixed up together. Similar changes may be met with in the quieter forms of fat necrosis."

That this condition is not so uncommon as supposed is also evidenced by a table published by Lee and Adair[2] in the article already referred to. During the period in which their five cases of fat necrosis occurred they found that, compared with primary breast cancer, the incidence was 1.8 per cent., with operable cases of breast cancer 4.2 per cent., and compared with benign lesions the incidence was 7 per cent.

The following case recently came under my care:

Clinical History of Case.

Mrs. E. A., aged 53, no children. Rather an obese subject. She knocked her right breast two months previously to noticing a lump therein. On examination, there was a nodule about 1½ by 1½ in. in the upper and outer quadrant of her right breast; it was hard and fairly well defined, and could be easily felt with the flat of the hand. The centre of the nodule was attached to the skin, but there was no deep fixity, nor could any enlarged glands be felt in the axilla. The nipple was not retracted, nor was the breast elevated. The diagnosis of early carcinoma of the breast was made, and with this diagnosis two of my colleagues agreed. A radical removal of the breast was carried out. The convalescence was straightforward, and the patient was discharged three weeks later with a soundly healed wound.

Microscopic Examination.

The breast lesion is a subacute inflammatory and necrotic one, without evidence of neoplastic change, and involving the adipose rather than the glandular tissue.

1. In the central portion of the affected area there are several small necrotic patches of irregular outline, as yet free from calcification.
